¹ Content estimated at 70 percent.

² Content estimated at 80 percent.

A notable increase in consumption of antimony in 1936 is indicated by the 80-percent rise in the available supply of primary metal. This was brought about largely by an improved demand for antimonial lead and other alloys, although the manufacture of antimony compounds also consumed greater tonnages. In 1936, 4,852 tons of antimony oxide and other compounds, with an estimated antimony content of 3,940 tons, were produced, compared with 3,969 and 3,227 tons, respectively, in 1935.

Over half of the primary antimony consumed in the United States is used in the manufacture of such products as storage batteries, cable covering, and bearing metals, from which there is a large return of scrap. The constant recycling of this scrap provides industry with antimony products in addition to those made from primary metal. In 1936, 9,900 tons of secondary antimony were recovered, which was equivalent to 66 percent of the apparent consumption of new metal.

Some important changes have been made recently in the manufacture of electric storage batteries, one of the principal consumers of antimony. Due to greater load requirements of modern automobile batteries, the thickness of grids has been reduced to permit use of more plates without increasing the size of the battery. This has necessitated an increase in the tensile strength of the antimonial lead used for this purpose, which has been done by increasing the antimony content to 12 percent; formerly 6 to 9 percent was used. It has been known for some time that small amounts of the antimony in storage batteries enter the electrolyte and cause self-discharge of the battery when idle. This has not been troublesome in automobile batteries, but in some other installations it is a distinct disadvantage. To overcome this difficulty, lead alloy containing 0.1 percent calcium has been developed. Its adoption for use in automobile batteries is uncertain, as it is difficult to cast the alloy into the thin grids now required, and heat treatment is needed to provide strength equivalent to the antimonial lead grids now used. A cadmium-lead alloy is being used in submarine storage batteries in Germany.

The use of antimony fluoride as a mothproofing for fabrics has been described.² Antimony is said to be superior to arsenic as a preventive

² Textile Colorist, vol. 58, September 1936, p. 591.

of dezincification in the manufacture of copper-bearing-metal alloys containing zinc. A pewter composed of 5 percent antimony and 95 percent tin and with properties superior to those of the commonly used alloy of 2 percent copper, 6 percent antimony, and 92 percent tin, has been developed.

FOREIGN TRADE

The following tables show imports and exports of antimony and antimony products.

PRICES

The average New York price for Chinese antimony in 1936 was 12.97 cents per pound (duty paid), a decline of 8 percent from 1935. The quotation at the beginning of the year stood at 14 cents, which proved to be the high for the year. The downward trend evident in the last quarter of 1935 continued into 1936. Weakness in the Chinese market was reflected in the sharp decline in New York quotations to 12.625 cents during the first part of January, but toward the latter part of the month the market strengthened and by March the price had risen to 13.50 cents, at which level it remained throughout April and May. During June, however, political conditions in China prompted some liquidation of stocks held at Changsha, and by the early part of August the New York price had declined to 12.50 cents, the low for the year. There was no change during September, October, and November, but early in December the price began to move upward, largely on account of general consumer and speculator interest in other nonferrous metals. At the close of the year the quotation stood at 13.75 cents.

Quotations for domestic metal ranged from 10.625 cents in August to 13.75 cents at the close of the year and generally were below the quotations for Chinese metal. The average price for American brands during 1936 was 12.25 cents, or 0.72 cent below the average quotation for Chinese brands.

On the London market quotations on English brands ex warehouse opened at £76 to £77 per long ton and closed at £72 to £73. The opening price was also the high for the year, and the low of £64½ to £65½ was established during the latter part of July and held during August and September. Price ranges on foreign brands ex warehouse were as follows: Open and high £65, low £51, and close £60 to £61. In China, prevailing prices for antimony c. i. f. Hankow were considerably higher at the close of the year than at the beginning. On December 31, 1935, the price was equivalent to \$214 (U. S. currency) per long ton, compared to \$236 on December 31, 1936. At the end of July the quotation stood at \$183.

Average monthly quoted prices of antimony, prompt delivery at New York, 1929-36, in cents per pound ¹

⁶ Less than 1 ton (434 kilos).

the 1929 output. Statistics shown herein do not include antimony derived from lead ores, which probably seldom exceeds 5,000 tons per year. China's output decreased slightly, but in 1936 it continued to be the principal producer, having contributed 53 percent of the estimated total; in 1929 China's share was 71 percent. Loss of markets in the United States has been the principal reason for the decline in China's importance in the antimony trade. Mexico, Bolivia, Peru, Yugoslavia, and the United States mined considerably more antimony in 1936 than in 1935.

REVIEW BY COUNTRIES

Austria.—In October 1936 it was reported that operations had been resumed at the Szalonak mines in the Burgenland district.

Australia.—Wiluna Gold Mines, Ltd., completed a lead smelter to treat stibnite concentrates from the Moonlight mine, arsenopyrite from the Wiluna mine, and lead ores from mines recently acquired at Northampton, Western Australia.

China.—Over 95 percent of the antimony produced in China comes from the Province of Hunan. As the industry is important in the economic life of the Province, the decline in the price of antimony during the depression caused considerable hardship. With a view to ameliorating the situation, the Provincial Government early in 1933 organized the Antimony Trade Association for Hunan, later known as Hunan Antimony Syndicate. The syndicate was established for the purpose of collecting taxes for the Provincial Government and to exercise control over the industry. The latter objective did not prove to be very effective. Several unsuccessful attempts were made to restrict production and maintain prices. In December 1935 the National Government of China assumed control of the industry, abolishing the old syndicate and creating an Antimony Administration under the National Resources Commission. According to some sources, this move was prompted primarily by a desire to divert to the National Government the taxes collected by the Provincial Government.

The new administration immediately established production and export quotas, and during the first quarter of 1936 dealers found it difficult to obtain enough export permits to meet the growing demands of world trade. This difficulty was remedied during the second quarter of the year. During the third quarter speculators became active in the local markets. It was reported that 3,000 of the 4,400 long tons of antimony on hand in China were owned by speculators intent on raising local prices. Daily transactions on the Changsha market, mostly between local dealers, often totaled 500 to 700 tons, whereas the daily production of metal was less than 50 tons. The speculative market thus created was opposed by the National Antimony Administration, and at the close of the year drastic measures were taken to reduce prices and bring some degree of stability to the market. It was reported that, effective January 1, 1937, permits to ship antimony from Hunan Province would be issued only to the Antimony Administration. Prices were established for the purchase and sale of antimony. On January 1, 1937, the price for regulus payable to miners and smelters was set at Ch \$450 per ton, c. i. f. Changsha, which was considerably below the Ch \$800 currently quoted on the Hankow market. The announced selling price on the same date at

Changsha was Ch \$618. An office was set up at Hankow to receive and execute orders from local exporting firms and concerns abroad wishing to purchase antimony. It is expected that the office will deal directly with buyers in foreign countries, and to this end a commission is to be sent abroad to encourage direct transactions.

The foregoing actions of the Administration met with considerable opposition from dealers and producers. It was evident that the policy of the administration was to eliminate the Changsha dealers from the trade entirely. The producers felt that in offering such low prices the administration was absorbing profits that should accrue to them. It was reported that as a defense measure producers had agreed to make no sales to the administration and to curtail production sharply so that the administration would be unable to obtain supplies to sell to local exporters. The administration countered with a threat to take over the mines if the measures adopted by the producers proved to be effective. While details as to the outcome of the controversy are not available at this time, the decline in estimated production in Hunan from 1,200 long tons in December 1936 to 650 tons in January 1937 and a subsequent rise to 1,100 tons in April suggests that the producers may have carried out their program partly. This is indicated further by the large increase in stocks of metal at the mines and the virtual depletion of supplies at Changsha and Hankow during the first 3 months of 1937 and the cessation of shipments from Changsha in April.

According to United States Vice Consul Arthur R. Ringwalt, of Yunnanfu, the rise in the price of antimony during the last 2 years has stimulated interest in the antimony deposits of Yunan Province. The richest deposits are found in the neighborhood of Chihtsum on the Yunnan Railway near Mengtsz and Lusi 80 miles to the north of Chihtsum. Other deposits occur near Yenshan 50 miles east of Chihtsum. A small amount was produced in 1936. Operations appear to have been halted by the establishment of a Government monopoly to control production of tungsten ores as well as antimony. It is believed that the Province will be a marginal producer at best.

Colombia.—Late in the year it was reported that an antimony mine was being developed in the State of Tolima.

Japan.—The Japanese Antimony Mining Co. is planning a new refinery at Amagasaki, Hyogo Province.

Mexico.—The production of antimony in Mexico has increased considerably during the last few years, owing largely to the greater requirements of the antimony smelter at Laredo, Tex. The principal mines are situated in the Catorce district, San Luis Potosi, and some ore is produced in the Atlas district, Sonora. Metallic antimony is produced in Mexico as a byproduct of lead ores at the Monterrey smelter of the Compania Minera de Penoles, S. A.

U. S. S. R. (Russia).—A trial plant for the production of 70 metric tons of metallic antimony annually was reported under construction at Kadamzhai, South Kazakstan. At Turgai, North Kazakstan, a smelter has been producing antimony trisulphide since the end of 1935, and by the end of 1936 a second plant will be producing metallic antimony and antimony pentoxide.

Yugoslavia.—The Podrinje Consolidated Mines, Ltd., under British management, has resumed operations at its antimony, lead, and silver mines at Krupanj and Stolic. In the latter mines the ore is said to contain 25 to 30 percent antimony. A new plant with a

daily capacity of 4 tons of antimony (99.6 percent pure) has been completed.

CADMIUM

Production and consumption of cadmium in the United States established new peaks in 1936. Consumption throughout most of the year was so heavy that domestic producers, with stocks depleted by the record sales of 1935, were unable to meet the demand. Consequently, there was a large increase in imports. Prices broke sharply about the middle of the year, but the average for 1936, 97.8 cents per pound, was considerably above the 70.5 cents recorded for 1935. Average values realized by producers on sales of metal, however, were below quoted averages. Partial returns received by the Bureau of Mines indicated average selling prices of about 80 cents in 1936 and 50 cents in 1935. At the close of the year producers' stocks were exhausted.

High prices and scarcity of supplies have retarded development of new uses and forced substitution in some of the old ones. Bright zinc coatings have replaced cadmium plating in many instances, and other materials have been substituted for cadmium pigments to some extent. The concern that pioneered in the use of cadmium alloys in automobile bearings reverted to tin-base alloys in 1936. Although other manufacturers have adopted cadmium bearings, the threatened loss of this market precipitated the price drop mentioned previously.

In Europe production exceeded demand during the first 9 months and prices at London declined from \$1.21 in February to 57 cents in September. In the last quarter sales increased rapidly, so that by the close of the year stocks were exhausted and the price had risen to 98 cents. World production increased 17 percent in 1936.

Cadmium produced, sold by producers, imported, and consumed in the United States, 1929-36, in pounds

Chemical & Pigment Co.....	Baltimore, Md.
E. I. du Pont de Nemours & Co.....	Cleveland, Ohio.
Harshaw Chemical Co.....	Elyria, Ohio.
New Jersey Zinc Co.....	Palmerton, Pa.
Sherwin-Williams Co.....	Chicago, Ill.
St. Joseph Lead Co.....	Herculeanum, Mo.
Sullivan Mining Co.....	Kellogg, Idaho.
United Color & Pigment Co.....	Newark, N. J.
U. S. Smelting, Refining and Mining Co.....	Midvale, Utah.

Domestic production of primary cadmium is derived from the treatment of flue dust from copper and lead smelters, as a byproduct from the smelting and electrolytic reduction of zinc ores, and from the purification of zinc sulphate solutions used in the manufacture of lithopone. Thus, further expansion of cadmium production depends largely on increases in the output of copper, lead, and particularly zinc.

Of interest as a potential means of obtaining an additional source of supply is the Queneau process for removing cadmium and other metals from zinc concentrates. A cheap chloride is added to the roasted concentrate, and the mixture is subjected to a blast roast that volatilizes as chlorides the cadmium and other contaminating metals. The fume is collected and treated further for the recovery of the various metals. The process, which is described in United States Patent 1999209, April 30, 1935, is said to present a method of recovering much of the cadmium that now goes into prime western grades of zinc. A similar process, in which fluorides are used instead of chlorides, also has been proposed for the recovery of cadmium from zinc ores (United States Patent 2064835, December 22, 1936).

A small quantity of secondary cadmium is recovered from the scrap from the manufacture of automobile bearings. This is not included in the statement of production, as it would represent duplication of metal previously reported.

DOMESTIC CONSUMPTION

Cadmium is used principally in the manufacture of alloys and compounds and as a plating material. Prior to 1935 the latter use was the most important, but in that year the adoption of cadmium alloys for bearing metals by some automobile manufacturers raised this use of the metal to first place. The resulting shortage of supply and rise in price forced the substitution of zinc in plating in many cases.

According to some authorities, the superiority of cadmium over zinc in platings has been exaggerated. Diggin³ suggests that the bright coatings obtained with cadmium proved to be more salable than the dull finishes formerly obtained with zinc. This advantage,

³ Diggin, M. B., Recent Developments Open Path to Wider Use of Bright Zinc Plating: Steel, vol. 98, no. 16, Apr. 20, 1936, p. 44.

however, has disappeared since the development of bright zinc coatings. Cadmium coatings formerly were applied more easily, but this advantage likewise has been eliminated to some extent by improvements in zinc-plating technique.

Soderberg,⁴ on the other hand, states that the substitution of zinc in plating was due to the increased consumption of cadmium in other industries, and that the advantages of cadmium plating will again lead to its greater employment for various purposes. He points out that the brightness of cadmium plating is more permanent than that of bright zinc coatings. Cadmium withstands corrosion better than zinc under certain conditions, such as in alkaline solutions. The low electrical contact resistance between cadmium-plated surfaces and the ease with which they can be soldered are factors that favor the use of cadmium. He also claims that cadmium plating can be done more easily than zinc plating.

Corrosion tests on cadmium and zinc coatings on steel conducted by the Bureau of Standards⁵ indicated no significant difference in the two metals in mild or marine atmospheres. In industrial areas where the air was contaminated with sulphur compounds zinc was superior to cadmium. A coating consisting of about 10 percent cadmium and 90 percent zinc was found to be superior to either zinc or cadmium.

R. J. McKay and R. Worthington have presented a summary and bibliography of cadmium plating in chapter 8 of Mimeograph Series 71, entitled "Corrosion Resistance of Metals and Alloys", published in 1936 by the American Chemical Society.

The future of cadmium alloys in automobile bearings seems to depend upon the ability of producers to furnish adequate supplies of the metal at prices below those prevailing in recent years. According to some reports, several firms have deferred adopting cadmium alloy because the supply is uncertain, and some companies recently discontinued using cadmium bearings. The problem of producing lubricants that will not corrode cadmium alloys apparently has been solved. Ordinary tin-base bearing metals can be strengthened considerably by adding 1 percent of cadmium.

The development of cadmium-zinc solders for aluminum and sheet steel was reported in 1936.

The use of cadmium in compounds increased in 1936. Production of cadmium lithopone, which was curtailed sharply in 1935 because of shortage of supplies, increased materially, and the manufacture of sulphides increased substantially, also.

FOREIGN TRADE

Official statistics record only the imports of metallic cadmium. There is some import and export trade in cadmium compounds and some metal is known to have been exported in former years, but the quantities involved are believed to be relatively unimportant. Imports of metallic cadmium increased 211 percent in 1936. Of the 576,139 pounds received, Canada supplied 238,599, Belgium 170,656, United Kingdom 108,866, Norway 33,619, Germany 11,519, Australia 10,640, and Netherlands 2,240. The United States also imports crude

⁵ Blum, William, Strausser, Paul, W. C., and Brenner, Abner, *Corrosion-Protective Value of Electrodeposited Zinc and Cadmium Coatings on Steel: Jour. Research, National Bureau of Standards*, vol. 16, no. 2, February 1936, pp. 185-212.

materials containing cadmium for refining. In 10 months of 1936, Mexico reported exports of approximately 500 tons of cadmium to the United States.

PRICES

According to Engineering and Mining Journal, the average price of cadmium in 1936 was 97.8 cents per pound, compared with 70.5 cents in 1935 and 55 cents from 1931 to 1934. In 1929 the price ranged from 80 to 95 cents per pound. Incomplete data obtained from producers by the Bureau of Mines indicate that the average value realized on sales of metallic cadmium in 1935 was about 50 cents per pound and in 1936, 80 cents.

The quoted price of cadmium was maintained at \$1.025 to \$1.05 per pound for the first 5 months of 1936. During this period it was rumored that some automobile manufacturers using cadmium bearing metals were threatening to revert to the use of tin-base metal on account of the high price of cadmium and constant shortage of supplies. About the middle of June, in an effort to prevent this move, producers reduced the price to bearing makers to 75 cents for large-scale transactions. The price to platers remained the same. On July 16, E. and M. J. Metal and Mineral Markets began to quote small parcels, spot, at \$1.05 and quantity business for nearby and forward delivery at 75 cents to \$1. These quotations held for the balance of the year, although on July 30 the designations were changed to "spot lots to platers, patented shapes, \$1.05" and "quantity business, commercial sticks, prompt and forward shipment, 75 cents to \$1".

On the London market the demand for cadmium continued good, but additional supplies that came into the market from new producers sent prices down from a high of 4 s. 10 d. (\$1.21 per pound) in February to a low of 2 s. 3 d. (\$0.57) in September. The low price stimulated consumption and diverted some foreign supplies from the European market. Supplies again became scarce, and as a consequence prices moved up. At the close of the year the quotation stood at 4 s. (\$0.98).

WORLD PRODUCTION

World production of cadmium in 1936 is estimated at 3,665 metric tons, 17 percent more than in 1935. The United States contributed 53 percent of this total, but some of it was derived from cadmium materials imported from Mexico. All the countries for which 1936 data are available, except Norway and South-West Africa, made substantial increases in production. South-West Africa ships cadmium-bearing flue dusts to Germany for treatment, but German production statistics apparently do not include the cadmium derived therefrom.

¹ Exports of domestic product. Production figures not available.² Data not available. Estimate included in total.³ Estimated production.⁴ The Mexican Government reports the total cadmium content of material produced in Mexico as follows: 1929, 640,968 kilos; 1932, 86,174 kilos; 1933, 502,160 kilos; 1934, 334,714 kilos; 1935, 597,527 kilos; and 1936, 537,017 kilos. This material is exported for extraction elsewhere; therefore, to avoid duplication of figures, the data are not included in this table.⁵ Estimated cadmium content.

REVIEW BY COUNTRIES

Australia.—Cadmium is recovered as a byproduct from zinc ores treated at the electrolytic zinc plant at Risdon, Tasmania. Greater production in 1936 reflects the larger output of zinc in that year.

Belgium.—The principal producer is Vieille Montagne. In 1936 Compagnie Overpelt Lommel et Corphalie began production of high-grade metal at its Campine plant.

Canada.—The cadmium plant of the Hudson Bay Mining & Smelting Co., Ltd., was put into operation during 1936, thus increasing the supply of metal from this country. Formerly the Trail plant of the Consolidated Mining & Smelting Co. of Canada, Ltd., was the only producer.

Germany.—Increased supply from the new Magdeburg plant has stimulated the substitution of cadmium for tin in solders and bearing metals as Germany relies largely on imports for her tin. The Magdeburg plant has an annual capacity of 150 to 180 tons of cadmium and operates on residues obtained from the treatment of Upper Silesian zinc-blende concentrates, which contain approximately 0.25 percent cadmium.

Mexico.—Considerable cadmium is recovered from flue dusts collected at Mexican smelters and exported to other countries for treatment. For 1936, production is estimated at 535 metric tons of metal. Exports were approximately 500 tons, all of which went to the United States.

South-West Africa.—320 tons of smelter-flue dust containing 30.46 percent cadmium were shipped to Germany from stocks at the Tsumeb mine. The sharp decline in shipments in 1936 suggests that this source of supply is approaching depletion.

U. S. S. R. (Russia).—Cadmium is produced at the Ridder, Orzhonikidzi, and Cheliabinsk plants; the last was completed only recently.

United Kingdom.—Imperial Smelting Corporation, Ltd., completed a new plant for the production of cadmium during 1936; full-scale operation was expected early in 1937.

Although platinum occurs over a wide area in Alaska, California, and Oregon (the chief producing localities of this country), the proportion of the platinum metals present usually is small, and the deposits could not be worked profitably if it were not for the gold content. The quantity of platinum metals recovered annually from these placer deposits averaged about 1,200 ounces during the decade 1926-35 and was an almost negligible part of the world supply. Considerable quantities—775 ounces in 1924, 2,842 ounces in 1925, 3,330 ounces in 1926, and 108 ounces in 1927—of palladium formerly were recovered from domestic palladium-bearing copper ore, but none has been recovered since 1927. Much larger quantities of platinum metals are obtained in the United States as byproducts of gold and other metals (about 6,100 ounces annually during the 10 years 1926-35), but the total output from domestic sources has slight importance compared with domestic consumption. However, in 1934 and 1935 larger quantities of platinum metals were recovered from domestic placer deposits (2,416 ounces and 6,748 ounces, respectively) than were obtained as byproducts of gold and other metals (2,335 ounces in 1934 and 2,483 ounces in 1935). The United States, nevertheless, is an important contributor to the world supply of refined new metals, as it has furnished about 47,600 ounces annually for 1926-35. The bulk of the output comes from crude platinum imported from foreign sources, notably Colombia. In addition, this country has supplied about 46,600 ounces of secondary platinum metals annually from 1926 to 1935.

It is estimated that the world's known workable deposits of platinum can supply annually about 400,000 ounces of new platinum and about 70,000 ounces of palladium. Canada can furnish about 125,000 ounces of platinum; Colombia, 50,000 ounces; U. S. S. R. (Russia),

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

150,000 ounces; Union of South Africa, 50,000 ounces; and the rest of the world, about 25,000 ounces. Canada also can produce about 60,000 ounces of palladium annually and the remainder of the world about 10,000 ounces.

¹ In 1935 includes 6,593 ounces of new platinum from domestic sources, comprising 5,232 ounces derived from crude placer platinum and 1,361 ounces obtained from domestic gold and copper ores as a byproduct of refining; in 1936 includes 7,355 ounces of new platinum from domestic sources, comprising 2,880 ounces derived from crude placer platinum, 32 ounces recovered from ore, and 4,443 ounces obtained from domestic gold and copper ores as a byproduct of refining.

² Exclusive of exports by parcel post.

CRUDE PLATINUM

Production.—Mine returns for 1936 indicate a production of 8,825 troy ounces of crude platinum in Alaska, 900 ounces in California, and 60 ounces in Oregon—a total of 9,785 ounces (9,069 ounces in 1935). The greater part of the production in Alaska came from placers in the Goodnews Bay district south of the mouth of the Kuskokwim River, but small quantities were recovered in placer-gold mining in the Koyuk district, Seward Peninsula, and in reworking the tailings from earlier lode-mining operations in the Ketchikan district, Kasaan Peninsula. In California most of the platinum produced was a byproduct of dredges working the gold placers in Merced, Sacramento, Stanislaus, and Yuba Counties. Production in Oregon came mainly from the ocean beach near Cape Blanco in Curry County.

Many gold and copper ores in the United States contain comparatively small quantities of platinum. These ores usually furnish the greater part of the new platinum recovered annually from domestic sources. In 1934 and 1935, however, much the greater part of the new platinum recovered from domestic sources was placer platinum. For example, 1,914 and 5,232 ounces, respectively, of platinum were recovered from placers in 1934 and 1935 and 1,062 and 1,361 ounces, respectively, as a byproduct of refining gold and copper ores in 1934 and 1935.

Purchases.—Platinum refiners in the United States reported purchases of domestic crude platinum from the following sources in 1936: Alaska, 3,174 ounces; California, 926 ounces; Oregon, 80 ounces; and unspecified, 21 ounces—a total of 4,201 ounces (7,730 ounces in 1935).

Refiners in the United States also reported purchases of 42,042 ounces (44,642 ounces in 1935) of foreign crude platinum in 1936—4 ounces from Canada, 37,949 ounces from Colombia, 1,312 ounces from Ethiopia, and 2,777 ounces from South Africa.

Markets and prices.—Returns received from the sale of crude platinum are disappointing to miners who are unaware that quotations usually refer not to the price of the metallic content of crude platinum but to that of the pure metals that have been subjected to treatment costs.

Sellers of domestic crude platinum reported that they were paid for metal content based on assay. Buyers reported purchases at \$18 to \$46.54 an ounce for domestic and \$23.28 to \$39.87 an ounce for foreign crude platinum. A list of refiners in the United States who purchased foreign and domestic crude platinum in 1936 follows:

American Platinum Works, 225 New Jersey Railroad Avenue, Newark, N. J.
 Baker & Co., Inc., 54 Austin Street, Newark, N. J.
 Sigmund Cohn, 44 Gold Street, New York, N. Y.

 S. B. Gracier & Sons, 212 Stockton Street, San Francisco, Calif.
 Kastenhuber & Lehrfeld, 24 John Street, New York, N. Y.
 Pacific Platinum Works, Inc., 814 South Spring Street, Los Angeles, Calif.
 Western Gold & Platinum Works, 589 Bryant Street, San Francisco, Calif.
 Wildberg Bros. Smelting & Refining Co., 742 Market Street, San Francisco, Calif.

REFINED PLATINUM METALS

New metals recovered.—Reports from refiners of crude platinum, gold bullion, and copper indicate that 46,946 ounces of platinum metals were recovered in the United States from these sources in 1936, an increase of 12 percent compared with 1935. It is estimated that 12,720 ounces of the total in 1936 were derived from domestic sources.

FIGURE 43.—Average monthly prices per troy ounce of platinum and allied metals at New York, 1932-36.

Prices.—Refiners reported the following prices for platinum in 1936: High \$70, low \$26.81, and average for the year \$41.76 an ounce, compared with \$40, \$25.66, and \$32.60 an ounce, respectively, for 1935. They gave the following prices for palladium: High \$26, low \$18, and average for the year \$23.03 an ounce, compared with \$26, \$18, and \$23.25 an ounce, respectively, for 1935.

Refined platinum in 3-ounce bars was made available for speculative and investment buying in 1936. Chiefly because of such speculative flurry and improvement in world demand, the price of platinum

advanced from \$33 an ounce in April to \$70 an ounce in September, but toward the end of the year it dropped to \$48 an ounce. The price of iridium rose from \$55 to \$175 an ounce during the period of heavy demand.

Figure 43 shows the average monthly official prices quoted for platinum metals from 1932 to 1936.

Consumption.—The next table shows sales of platinum metals to consumers by refiners in the United States in 1935 and 1936. The figures include sales (by refiners in the United States) of platinum metals recovered from crude platinum, from gold bullion, from copper and nickel bullion and matte, from electrolytic muds, and from scrap materials and sweeps; in addition, they include sales of considerable quantities of imported platinum metals that are handled by refiners in the United States. Sales of platinum metals by refiners in the United States increased from 125,064 ounces in 1935 to 164,847 in 1936.

The uses of the platinum group are many and varied. The most widely used metal of the group is platinum itself, which constituted 112,447 ounces (68.2 percent) of the total platinum metals sold by domestic refiners in 1936. The largest user of platinum is the jewelry industry, where it is favored for engagement and wedding rings and finer settings. It is also used in collar pins, cuff links, pencils, and knives. Platinum-clad nickel is used for dresser sets, after-dinner coffee services, trophies, medals, and watchcases. Sales of platinum by domestic refiners to the jewelry industry were 50,936 ounces in 1936 (56,182 ounces in 1935). The second largest consumer of platinum in 1936 was the chemical industry, which used the metal chiefly as a catalyzer in the manufacture of sulphuric, acetic, and nitric acids; as a still for sulphuric acid; as an anode for electrochemical processes; and as chemical ware in the form of crucibles, dishes, and other laboratory equipment. The dental industry, in which platinum is used chiefly in posts and pins for artificial teeth, ranked third as a consumer in 1936. The electrical industry was the fourth largest consumer of platinum in 1936; the metal was used chiefly in contact points, telephone and telegraph apparatus, and magneto contacts.

Next to platinum, palladium is the most extensively used metal of the platinum group; it constituted 45,539 ounces (27.6 percent) of the total platinum metals sold by domestic refiners in 1936. It is by far the cheapest metal of the platinum group, especially volume for volume, and tends more and more to replace other metals. The largest consumer of palladium in 1936 was the dental industry, which purchased 25,481 ounces from domestic refiners compared with 20,916 ounces in 1935, 19,555 ounces in 1934, and average annual purchases of about 13,200 ounces during the 5-year period 1929–33. Palladium and platinum are standard materials in the preparation of dental alloys, as they are strong and impervious to attack by the acids in the mouth and can readily be cast and shaped to the complex forms required. The fact that dental alloys of high palladium content are less conspicuous than gold, are nontarnishable, and are economical, especially when palladium replaces a considerable quantity of gold, has led to an increase in the demand for palladium in dentistry. The electrical and jewelry industries are the next largest users of palladium, and small quantities are used in the manufacture of chemical ware and for miscellaneous purposes. Appreciation by the public of the fact that palladium has the same handsome color as its better-known

related metal, platinum, and is highly resistant to corrosion and tarnish as well, has resulted in greater use of the metal in jewelry. The gain (from 5,490 ounces in 1935 to 13,297 ounces in 1936) in sales of palladium to the electrical industry is noteworthy. Palladium leaf, first introduced in 1933, is being more widely accepted in diverse fields. Like gold, palladium can be beaten successfully into leaf for use for decorative effects on shoes, hats, gloves, pocketbooks, picture frames, and display signs. Novel applications recently have been as trim for lighting fixtures, for striping and lettering trains, and as a surface for the ceiling of a room in a Federal structure. Some palladium-clad molybdenum has been produced for special purposes.

The uses of iridium are few compared with those of platinum and palladium, but it ranks third among the platinum group as to consumption. Of the total sales of platinum metals in 1936, 4,390 ounces (2.7 percent) were iridium. It is employed chiefly as a hardener for platinum, principally in the manufacture of jewelry, in which a 10-percent iridium alloy is used, and in the electrical industry, in which an alloy containing 15 percent or more iridium is used. Some iridium is used in making fountain-pen points.

The consumption of the other platinum metals—osmium, rhodium, and ruthenium—is very small, amounting to only 1.5 percent of the total consumption of the group in 1936. Because of its brilliance and durability, rhodium has been called “the diamond of the metals.” As rhodium is one of the whitest and hardest of all metals and never tarnishes, rhodium plating is being used more and more as a finish for jewelry and silverware and for surfacing reflectors in searchlights.

FOREIGN TRADE

Imports.—The following tables show imports into the United States of platinum metals, which increased from 164,149 ounces in 1935 to 210,440 in 1936. Chief sources of imported platinum metals in 1936 were the United Kingdom (172,367 ounces) and Colombia (29,119 ounces). Imports of crude platinum from Colombia increased from 25,440 ounces in 1935 to 29,119 in 1936. Imports of palladium (chiefly from the United Kingdom) increased from 26,579 ounces in 1935 to 38,842 in 1936. Imports of platinum metals from the U. S. S. R. (Russia) decreased from 25,033 ounces in 1935 to 4,750 in 1936.

Exports.—Although a complete record of exports of platinum in 1935 is not available because shipments by parcel post were not recorded, it is believed that the export trade in platinum increased notably in 1936. Exports of unmanufactured products were 55,454 ounces, of which Japan took 28,869 ounces, France 10,247 ounces, and the United Kingdom 8,187 ounces.

PRODUCTION IN FOREIGN COUNTRIES

Belgian Congo.—According to a report of the Imperial Institute:²

Platinum and palladium occur in association with the copper ores of Katanga and are recovered as a byproduct in the electrolytic refining of copper by the Société Générale Métallurgique d'Hoboken of Antwerp, Belgium. The ores are said to contain about four times as much palladium as platinum.

Platinum is also reported to occur in association with gold in the alluvials of Kilo, among the headwaters of the Ituri River, west of Lake Albert. A more interesting occurrence, however, is that at Ruwe, near the source of the Lualaba, in southwest Katanga, where platinum and palladium are associated with gold, silver, and more or less iron, cobalt, nickel, lead, and copper. The ore body occurs in an indurated, banded sandstone and is some 1,200 ft. in length, varying in width from 3 to 20 ft. with an average of 8 ft. The lead and copper occur as vanadates, while pyromorphite and malachite are present and are said to act as indicators. Platinum, palladium, and silver increase or decrease in quantity together, but gold values are said to be independent of these.³ Below the outcrop of the ore body is an eluvial deposit containing nuggets of gold up to 2 in. in diameter, but platinum seems to be practically absent.

According to the annual report of the Union Minière du Haut Katanga for 1908, the gold and platinum reef at Ruwe contains about 3 dwt. of gold and 9 dwt. of platinum metals per ton.

The eluvial deposit was worked for many years in the early part of the century, and at the present time the tailings dumps from these old workings are being treated for gold, while investigations are proceeding on the ore body itself.

The production of platinum and palladium was 965 and 5,144 ounces, respectively, in 1935 compared with 1,254 and 3,569 ounces, respectively, in 1934.

Canada.—Virtually the entire Canadian output of metals of the platinum group is recovered in refining nickel-copper matte from the Sudbury district of Ontario. Residues obtained in the metallurgical treatment of the nickel-copper matte are refined by the International Nickel Co. of Canada, Ltd., at its refinery at Acton, England, which has an annual capacity of 300,000 ounces of platinum-group metals. Recoveries of platinum metals from the nickel-copper ores in 1936 were 131,551 ounces of platinum and 103,671 ounces of other platinum-group metals compared with 105,335 ounces of platinum and 84,772 ounces of other platinum-group metals in 1935.⁴

British Columbia placers yielded only 39 ounces of stream platinum in 1936 compared with 20 ounces in 1935.

Colombia.—Colombia exported 38,333 ounces of crude platinum in 1936 (38,020 ounces in 1935), of which 20,765 ounces (23,363 ounces in 1935) were the output of dredges and 17,568 ounces (14,657 ounces in 1935) the product of hand-working by native operators.

The South American Gold & Platinum Co. produced 26,446 ounces of crude platinum and 48,036 ounces of crude gold in 1936 compared with 27,414 ounces of crude platinum and 44,846 ounces of crude gold in 1935.

Ethiopia.—The production of crude platinum in Ethiopia was 8,038 ounces in 1936 compared with 6,320 in 1935.

Germany.—Although the production of platinum metals in Germany is confined to small quantities of platinum and palladium recovered as byproducts in the treatment of copper ores, the country is important in the international platinum trade. It is the largest European

² Imperial Institute, Mineral Resources Department, London, Reports on the Mineral Industry of the British Empire and Foreign Countries, Platinum and Allied Metals: 1936, pp. 97-98.

³ Ball, S. H., and Shaler, M. K., Mining Conditions in the Belgian Congo: Trans. Am. Inst. Min. Eng., vol. 41, 1910, p. 195.

⁴ Dominion Bureau of Statistics, Preliminary Report on the Mineral Production of Canada During the Calendar Year 1936: Ottawa, 1937.

consumer of platinum and has an important fabricating industry. Before the World War, Germany had an important platinum-smelting industry at Hanau, a suburb of Frankfurt-am-Main, which depended chiefly on the U. S. S. R. for its crude material. After the war, Russian platinum was distributed in the form of metal, and Germany had to discontinue smelting the ore. The plants at Hanau, however, import platinum metals, which are fabricated into products for various industries.

Imports of platinum metals and alloys into Germany increased from 84,981 ounces in 1935 to 525,883 in 1936. The chief sources of supply in 1936 were U. S. S. R. (451,567 ounces) and Great Britain (42,770 ounces). The U. S. S. R. (23,959 ounces), Switzerland (22,174 ounces), and Great Britain (20,747 ounces) were the chief sources of supply in 1935. The phenomenal gain in imports into Germany in 1936 was reported to be due to the inclusion of certain platinum-bearing material, such as platinum sweeps, electrolytic muds, used-up platinum contact material, and scrap, which should properly be classified elsewhere.

Exports of platinum metals and alloys from Germany decreased from 102,288 ounces in 1935 to 32,553 in 1936. Great Britain received only 3,733 ounces in 1936 compared with 50,573 in 1935. Presumably the large exports to Great Britain in 1935 were due to the transfer from Berlin to London of platinum belonging to the Soviet Government.

The following table on platinum metals and alloys imported into and exported from Germany indicates the trend in consumption, because the country depends almost entirely on imports.

Platinum metals and alloys imported into and exported from Germany, 1932-36, in ounces

Year	Imports	Exports	Year	Imports	Exports
1932-----	107,605	22,342	1935-----	84,981	102,288
1933-----	114,151	82,177	1936-----	525,883	32,553
1934-----	73,641	72,304			

¹ Includes platinum sweeps, electrolytic muds, used-up platinum contact material, and scrap.

Sierra Leone.—The production of crude platinum in Sierra Leone in 1936 was 484 ounces compared with 750 in 1935.

Tasmania.—The production of osmiridium in Tasmania in 1936 was 281 ounces compared with 235 in 1935. The Adams River field continued to be the chief producing area, although the northwestern fields yielded small quantities.

Union of South Africa.—According to the Department of Mines and Industries, sales of platinum in South Africa in 1936 were 29,044 ounces valued at £176,292 (£6.07 an ounce) compared with 31,338 ounces valued at £179,697 (£5.73 an ounce) in 1935. The average composition of the product shipped in 1935 was platinum 77.75 percent, palladium 15.82 percent, iridium 0.05 percent, ruthenium 0.91 percent, and gold 5.47 percent.

Sales of osmiridium in 1936 amounted to 5,018 ounces valued at £27,297 (£5.44 an ounce) compared with 5,278 ounces valued at £24,460 (£4.63 an ounce) in 1935. The average composition of the product shipped in 1935 was osmium 32.79 percent, iridium 28.45

percent, ruthenium 13.15 percent, platinum 11.26 percent, gold 0.52 percent, rhodium 0.55 percent, and undetermined 13.28 percent.

U. S. S. R. (Russia).—No authentic statistics on the production of platinum in the U. S. S. R. in recent years are available. However, it is generally estimated that an annual output of 100,000 ounces of crude platinum has been maintained.

For thousands of years the world's needs with respect to metals were supplied mainly by iron, copper, lead, and zinc supplemented by small amounts of tin and antimony. Even as recently as the beginning of the present century gold, silver, platinum, and a few minor elements virtually completed the list of useful metals. The sharp rise in factory production during the nineteenth century resulted in an enormous increase in demand for fuels and metals, but no corresponding increase occurred in the variety of metals in general use. Since 1900, however, the number of metals in active use has more than doubled, and research still proceeds swiftly to expand our knowledge and, if possible, our utilization of all the 92 elements. Discovery of uses for byproduct metals recovered from wastes of smelting and refining industries has been largely responsible for the wider utilization of the less well-known metals.

This review includes several elements, such as barium and sodium, whose compounds, in the form of nonmetals (for example, barite and salt), are discussed in other chapters of this volume. Several of the more important so-called "minor" metals likewise are discussed in separate chapters, including some that were covered in the Minor Metals chapter of former volumes of Minerals Yearbook. The present review, however, includes a rather large number of less well-known or really rare elements that have not been mentioned hitherto in this series. The Bureau of Mines receives numerous inquiries regarding all the elements, and this chapter is intended to meet the demand for information as to the commercial status of production and utilization of these miscellaneous metals.

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

A convenient classification of the elements is the periodic table credited to Mendeleef, wherein the elements are ranked in order of increasing atomic weight. For the greater convenience of nontechnical readers, however, the subsequent discussion takes up the specified metals in alphabetical order.

ACTINIUM

Actinium (element 89), is one of the disintegration products of uranium. Uranium ores contain actinium, but in much smaller quantities, even, than radium. According to some authorities, uranium decomposes into two series or families of radioactive elements, 97 percent going to form the radium series and 3 percent proceeding through the much shorter series of transformations that constitute the actinium series. Actinium has been extracted from pitchblende. It disintegrates rather slowly, requiring some $13\frac{1}{2}$ years to decay to half value, but none of the actinium series has much economic significance compared to radium or mesothorium.

ALABAMINE

In 1931, Dr. Fred Allison and coworkers at Alabama Polytechnic Institute reported the discovery, by magneto-optic methods, of element 85, which hitherto had been inferentially called eka-iodine, but which he named alabamine. If the identification of virginium is definitely accepted, alabamine was the last of the 92 elements to be discovered. Inasmuch as its existence in the earth's crust was long doubted, alabamine obviously is too rare even to be classed as a laboratory curiosity. The discoverer reports the preparation in his laboratory of a "concentrate" containing only about 2 parts of alabamine per million in the form of lithium alabamide. The greatest natural concentration hitherto found seemed to be of the order of 1 part in 100 million.

BARIUM

Barium (element 56) one of the alkaline-earth group, is a gray metal that melts at 850°C . and boils at $1,140^{\circ}\text{C}$. It looks like lead and is easily cut by a knife but is hardly one-third as heavy (specific gravity 3.5) and oxidizes rapidly. Formerly quite expensive—\$450 a pound, or more—barium was reduced in price to less than \$10 a pound in 1932 and now costs less than \$7.50. Barium compounds, being made from barite or witherite, are cheap, and the price of the metal could be reduced greatly if tonnage outlets could be found. For the present, however, there is little use for the metal except for ignition equipment; the nickel wire used for automobile spark-plug points frequently contains a small percentage of barium. A little of it has also been used for cleaning up the last traces of gas ("flashing") in vacuum tubes. However, aside from its extraordinary electron-emitting properties, barium metal inherently has little to recommend it commercially in lieu of calcium or even sodium, both of which can be made more cheaply per pound and are much more efficient for most chemical reactions. Even for certain thermionic emission purposes, barium compounds can be employed without first reducing them to the metal. At least two American companies have produced barium metal commercially, and it has been made, also, in Germany, France, Great Britain, and possibly other countries.

BERYLLIUM

Beryllium, or glucinum, as it is called in England (element 4), is a very light metal having about the same density as magnesium, although as rigid as steel, and possessing other interesting properties in its unalloyed state. Nevertheless, it seems destined always to be too expensive to be used extensively, except as a hardening agent for other metals. At present the rather small amount of beryllium consumed is principally in the form of beryllium-copper alloys containing about 2.25 percent beryllium. These alloys, properly heat-treated, have high tensile strength and remarkable ability to withstand repeated stress. They are widely employed instead of phosphor bronze in spring contacts, contact clips, and sundry small parts for office machines and other light mechanical devices. For many such purposes, where wear and corrosion resistance or high fatigue values, combined with good electrical conductivity, are essential, beryllium-copper has no real competitor, even though it costs 97 cents to \$1.50 a pound in standard commercial shapes and sizes—sheets, plates, rods, wire. It is nonmagnetic, and its nonsparking characteristics have led to its utilization in various safety tools, especially for use around gas works and petroleum refineries. Hand hammers, chisels, wrenches, wrecking bars, drift pins, and scrapers of beryllium-copper are on the market, and the alloy is used to make pistons for vibrators; firing pins in revolvers, rifles, and shot guns; precision bearings of various kinds; ball cages, bushings, platers' bars and cores, surgical instrument handles, and valve parts; and for wire cloth such as is used in the rubber industry for filtering abrasive materials, and possibly in paper-making machines. Of some importance is the use of the alloy for plastic molding dies; due to the higher heat conductivity of beryllium-copper (about twice that of steel), the cycle for certain plastic parts has been decreased to one-sixth of its former time.² The claim is made³ that copper-beryllium-cobalt alloys are cheaper than beryllium-copper alloys and are better conductors of electricity.

A great deal of publicity has been given the light-metal alloys of beryllium and their possible use in aircraft, but commercial developments have been unimportant. More promising is the use in iron alloys, particularly nickel-iron and nickel-chrome-iron. In Germany a good deal of work has been done on nickel-beryllium alloys, which are very strong. A nonmagnetic, highly corrosion resisting, beryllium-nickel-chrome-iron alloy is being used for heat-resistant springs and even for winding springs in watches.⁴ Small additions of beryllium have been made to silver to improve tarnish resistance, but the anticipated improvement did not take place under all testing conditions.

Beryllium metal has not been produced commercially in the United States, and world supplies have consisted chiefly of a 98-percent product made in small quantities in Germany since about 1927. In September 1935 the nominal quotation of this metal was dropped from 600 marks to 500 marks a pound. Master alloys of beryllium with copper, nickel, and iron have been made in the United States by the Beryllium Corporation of Pennsylvania, or its predecessor corporations

² Benford, F. G., Beryllium-Copper-Cobalt Alloys: *Metal Ind.* (London), vol. 49, no. 2, July 10, 1936 p. 40.

⁴ Stott, L. L., Properties and Alloys of Beryllium: *Am. Inst. Min. and Met. Eng. Tech. Pub.* 738 (Metals Technol.), 1936, 17 pp.

since about 1929 and have been sold at \$30 to \$40 per pound of contained beryllium. Until 1935, when its plant facilities were transferred from Marysville, Mich., to Temple, Pa., this company, which has a working agreement with the German producers, was the only producer of beryllium alloys in this country, but in that year the Westvaco Chlorine Products Co. entered the field. The operations of the latter company, however, are still more or less in the experimental stage. The Brush Beryllium Co., Cleveland, Ohio, has been an active producer of beryllium oxide and compounds for several years; and late in 1936, after developing a new process, it entered the metallic field, offering beryllium-copper master alloy at a new low price of \$23 per pound of beryllium content.

The commercial production of beryllium-copper alloys in the United States dates from 1932, or about the time that the reorganized Beryllium Corporation of America offered the American Brass Co. a 12- to 13-percent master alloy of good quality. The development of wrought alloys was begun under the direction of the late H. W. Bassett, but both the American Brass Co. and the Riverside Metal Co. have contributed to the rapid progress made in commercial production and sales of rolled and drawn products. Commercial castings also may be had at this time from several companies. The Beryllium Corporation of Pennsylvania offers three grades of heat-treated beryllium-copper castings; one of these has an ultimate tensile strength of 145,000 pounds per square inch with only 1 percent elongation, while another retains 75,000 pounds per square inch with 12 percent elongation.

Notwithstanding a voluminous patent literature, details as to commercial processes used in the manufacture of beryllium metal are not widely known. It seems to be generally assumed, however, that the Beryllium Corporation of Pennsylvania still makes the metal by electrolysis in a fluoride bath, whereas both the new producers employ nonelectrolytic processes with the oxide as a starting point.

Beryllium oxide has some highly useful properties—a melting point of about 2,570° C., great strength, low density, retention of electrical insulation properties at high temperature, and extraordinary resistance to thermal shock. For several years a relatively large proportion of the beryllium ores consumed in the United States has been made into beryllium oxide or other compounds for use chiefly as a superrefractory in crucibles, boats, electric-furnace walls, vacuum tubes, and electric-lamp parts. Recently,⁵ beryllium salts have been used instead of cobalt compounds to increase the light-fastness of lithopone, as they do not detract from the whiteness or brilliance. Sintered beryllium oxide is a high-duty abrasive suitable for grinding or polishing hard alloys.

According to the latest price list of the Brush Beryllium Co., beryllium oxide, fluffy, 99.8 percent, calcined at 1,450° C., for refractory crucibles and electrical insulators, can be bought at \$4 per pound in 100-pound lots; sodium-beryllium fluoride ($2\text{NaF} \cdot \text{BeF}_2$) for electrolytic or fluxing uses costs \$4.30 per pound (5-pound lots); beryllium nitrate ($\text{Be}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$) costs \$3 per pound (5-pound lots); and crystalline beryllium sulphate ($\text{BeSO}_4 \cdot 4\text{H}_2\text{O}$) for reagent use costs \$0.65 per pound (50- to 100-pound lots). Higher prices are charged for smaller quantities.

⁵ Chemical Trade Journal (London), Beryllium Compounds in Lithopone Industry: Vol. 99, no. 2576, Oct. 2, 1936, p. 286.

Beryl.—In 1936, beryl, the only commercial ore of beryllium, continued to be quoted at \$30 a short ton for the 10-percent BeO grade and \$35 a ton for 12-percent grade, f. o. b. mines. These quotations are nominal, and actual business is contractual. The New York delivered price in 1936 was around \$40 a ton. Whereas those who have beryl to sell may experience difficulty at present in disposing of their product promptly, the demand is growing, and a far better price would be paid to a shipper who could deliver regular shipments than to one who can offer only an occasional odd lot. Ore supplies long have been the main deterrent to more rapid development of the beryllium industry. Recently the situation has improved, but some of this loosening up of supplies has represented accumulations or recoveries from dumps at pegmatite mining operations in various parts of the world, and the question as to just how much newly mined beryl can be obtained regularly year after year has not been answered. The revival of lithium and feldspar mining in South Dakota has stimulated domestic production. Colorado, Nevada, and perhaps other States promise to yield substantial supplies, and small amounts already have been obtained in New England, New York, Virginia, and North Carolina. In Canada, the Renfrew Minerals, Ltd., organized in 1933, reported further development of its extensive pegmatite deposit during 1936.

American needs recently have been supplied principally from British India, but in 1936 imports amounting to 162 short tons valued at \$6,681 came from Argentina, except for small shipments from Brazil (3,241 pounds) and the Union of South Africa (11,091 pounds).

Brazilian beryl has been shipped to Europe, chiefly to Germany and Italy. South Africa, which produced 58 short tons and exported 22.4 tons assaying 12.3 percent BeO in 1935, seemed to be developing as a really important source, but the Namaqualand deposits, upon further investigation, appear to be unworkable until the general development of the area provides better transportation facilities. No reports have been received as to 1936 activity in Madagascar, an occasional producer. In Austria, the old Smaragd mine in Salzburg Province near Bramberg is again in operation, and small crystals have been recovered for the production of beryllium, according to a communication to the Bureau of Mines from Dr. Karl Mautner of Vienna.

Probably the best ore offered in the United States is from British India, which runs over 13 percent BeO, although some South American shipments run 12.2 percent compared with 11 to 11.5 percent for South Dakota beryl.

No statistics are available as to either production or consumption of beryl for the United States or for the world. Undoubtedly domestic consumption is increasing, having recently risen to perhaps 300 tons annually, while 500 tons annually is a reasonable prospect in the near future. The last figure represents a metal output of 25,000 to 30,000 pounds a year, which, at \$20 a pound, would indicate total gross sales of around \$500,000.

BORON

Although possessing many of the characteristics of a metal, boron (element 5), is more properly described as a "metalloid", a designation that it shares with such elements as arsenic, phosphorus, and sulphur, as well as with carbon, which it resembles in certain respects. Whereas the use of borax and sundry other boron compounds is increasing,

boron itself has few commercial applications. It is one of the hardest known substances, but for abrasive uses boron carbide is employed commercially—a compound that excels in hardness silicon carbide, tungsten carbide, artificial aluminous abrasives, sapphire, and, in fact, all known substances except the diamond. Boron alloys, which find a limited use in steel making and in the nonferrous-metals industries, are supplied by domestic manufacturers. Powdered boron (95 percent) is offered at \$25 a pound; boron carbide is worth around \$7 a pound; ferroboration (18 percent B) costs about \$5 a pound of alloy; and boron suboxide and boron fluoride (gases) also sell for \$5 a pound.⁶ Sodium borate (ordinary borax) sells by the ton at the equivalent of 2¼ cents a pound.

Imports into the United States in 1936 included 1,538 pounds of boron carbide valued at \$2,204 and 300 pounds of ferroboration valued at \$536. In addition, according to the Tariff Commission, 12,496 pounds of boron fluoride valued at \$10,053 came into the port of New York from Germany in 1936.

CAESIUM

Caesium, or cesium, (element 55) is an alkali-group metal so active chemically that, if unprotected, it will combine violently with the moisture, oxygen, and carbon dioxide of the atmosphere. Its salts are increasingly important, due to their use in the photocell industry. A "pill" composed of caesium chloride mixed with metallic magnesium or calcium may be introduced into certain kinds of radio tubes and flashed to coat the filament with caesium. According to more recent practice, however, caesium chromate is used instead of caesium chloride, and metallic silicon or tantalum instead of magnesium or calcium. In caesium photoelectric cells, without which we would have no talking motion pictures, the film of caesium formed on the silver or other base-metal electrode is only 1 molecule thick.⁷ A hint as to the magnitude of this business is given by the report⁷ that Russia alone is producing 800 grams of caesium salts a month and that Soviet needs already may be about 12 kilograms of caesium and rubidium annually and are likely to increase. In addition to their use as a gas absorber in radio tubes and to create a metallic vapor in power tubes and the important light-sensitive coating for the plates of photoelectric cells, caesium salts may be used in medicine, in fulminates, in fire-extinguishing compounds, and for sundry minor purposes. Metallic caesium has so low a melting point (28.5° C.) that it becomes liquid on a fairly warm day, and this, combined with the fact that it is costly to produce and difficult to protect from oxidation, discourages commercial use of the metal wherever its salts can be used instead. However, the metal can be purchased at \$1 a gram or less. Sometimes it is supplied in sealed capsules, which are filled with an oil. The principal compounds are the chloride and the chromate, both of which are offered at \$0.45 a gram.

Pollucite is the only mineral that can be considered primarily an ore of caesium. It occurs in certain pegmatites and has been mined in New England, but it is far from common. Caesium, however, also occurs in lithium ores, particularly lepidolite, from which it has

⁶ Quotations furnished by A. D. Mackay, New York, N. Y.

⁷ Fink, C. G., *Rare Metals and Minerals: Mining and Metallurgy*, vol. 18, no. 361, January 1937, p. 23.

been extracted commercially. Three companies, the Fansteel Metallurgical Corporation of North Chicago, Ill., the Maywood Chemical Co., Maywood, N. J., and the Calirare Chemical Corporation, Los Angeles, Calif., produce caesium salts in the United States. Caesium and its salts are also made in Germany, in the U. S. S. R. (Russia), and possibly in other European countries. Imports are not listed separately in the official statistics, but probably come only from Germany and are small in amount.

CALCIUM

Calcium (element 20) is the only alkaline-earth metal that has been used commercially on even a moderately extensive scale, and its consumption in the metallic condition still is small compared with the enormous consumption and cheapness of lime and other calcium compounds. It is fifth in order of abundance among elements in the earth's crust. Calcium metal is only about one and one-half times as heavy as water, melts at $810^{\circ}\text{C}.$, and boils around $1,440^{\circ}\text{C}.$ Although oxidizing quickly in the air and chemically active enough to decompose water, it can be handled without danger to the skin.

Ferrous metal and other lead alloys containing small percentages of calcium as a hardening agent have been in use for 20 years or more but are made by electrolyzing a lead bath covered with molten calcium chloride rather than by adding calcium metal. A long list of patents testifies to the vast number of potential uses of calcium, but specific uses⁸ are refining (debismuthizing) of lead, preparation of lead alloys, especially cable sheaths and battery plates, deoxidizing copper, preparation of copper alloys, making of bearing bronzes of the high-lead type, and deoxidizing and grain-refining cast iron, nickel, and nickel alloys, particularly iron-nickel and chromium-nickel. Calcium has been used also as a reducing agent in the preparation of chromium metal powder, thorium, and uranium, as an alloying, purifying, and modifying agent in aluminum, magnesium, and beryllium alloys; and as a "getter" in electrical discharge devices and vacuum tubes. Suggested uses include desulphurization and refining of petroleum and sundry extensions of its laboratory uses for removing from gases and liquids the last traces of oxygen, moisture, and other substances with which it reacts readily. Merely as a reducing agent, sodium is much cheaper and more efficient than calcium, but calcium has other advantages that tend to extend its uses, especially for several metallurgical purposes. Recently, calcium has been used in alloy steel—such as ordinary 18/8, 18/25 Cr, 8/10 Ni, 25/30 Ni, and free-cutting selenium-stainless steels—because it inhibits formation of carbides, promotes clean boundaries and uniform grain structure with no mottling or clouding, and makes unnecessary the addition of ferrosilicon. Certain chrome-nickel alloys may be forged after calcium treatment.

Until about 1918 the price of calcium metal was prohibitively high (it was unobtainable at less than about \$20 a pound), but later it was reduced to \$1.50, world production increasing gradually to possibly 25 tons a year, chiefly from France. The metal had been produced in this country only experimentally or on a very small scale before 1936, when the Electro Metallurgical Co. began making it at

⁸ Mantell, C.L., and Hardy, C., *Calcium, Its Metallurgy and Technology*: Electrochemical Soc. Preprint 66-18, 1934, p. 193.

Niagara Falls, N. Y., using calcium carbide instead of calcium chloride as the raw material. In quantities of 1 ton or more, calcium can be bought for 75 cents a pound.

Imports of calcium are reported under a general classification that includes barium, boron, strontium, tantalum, titanium, zirconium, and sundry other metals, the total imports for the group amounting in 1936 to only 17,118 pounds valued at \$13,219.

COLUMBIUM

Prior to about 1929, columbium (element 41), called niobium in Great Britain, had little or no industrial application. Except for about one-half ounce made in Germany in 1906, the metal had never been produced commercially until it was put on the market experimentally by the Fansteel Products Co. in 1928, although previously a small amount had been used in steel making in the form of a joint alloy with its sister metal tantalum, which accompanies it in most ores. In 1933, however, Becket and Franks reported their discovery that columbium inhibits intergranular corrosion of high-chromium steels, and subsequently ferrocolumbium has become an important alloy for the manufacture of weldable high-speed steels. In 1936 fully 40 tons of ferrocolumbium were sold in the United States, and the demand for columbo-tantalites increased substantially. Whereas only a few years ago the columbium content of even high-grade ores was not paid for, as much as £6 15s. a long-ton unit has been offered for mixed ores containing as low as 60 percent $\text{Cb}_2\text{O}_5 + \text{Ta}_2\text{O}_5$. American supplies of columbite are drawn from Nigeria, where the mineral, containing negligible amounts of tantalum, accompanies tin ore; 498 short tons of this columbite valued at \$257,666 were imported into the United States in 1936. The main producer is Jantar Nigeria Co., Ltd., which reports proved reserves of 6,000 short tons; other Nigerian producers are Minerals Research Syndicate, Ltd., African Prospectors, Ltd., Gold Coast Lands, Ltd., and West African Mines and Estates, Ltd. It is reported that columbo-tantalite likewise is being produced in the Belgian Congo as a byproduct of the tin operations of Geomines at Manono, Katanga. Ferrocolumbium, made only at Niagara Falls as a 50-percent alloy, sells for \$2.50 a pound of contained columbium. Columbium metal, now used in electronic tubes, is quoted at \$560 a pound for base sizes of rod and at \$500 a pound for sheet.

GALLIUM

Gallium (element 31) is a rare metal of the aluminum group, rather hard, but, like caesium, becoming liquid at a temperature only slightly above that of an ordinary room. It is a byproduct of the zinc industry and also occurs in some coal ashes. The price has been progressively reduced until now it could be bought in lots of several pounds at \$1.50 a gram, although about \$3 a gram is charged for the small quantities that suffice for ordinary experimental or educational laboratory needs. Outside of its occasional use in medium-high-temperature thermometers, for which purpose it is enclosed in quartz glass, gallium seems to have found no commercial applications.

GERMANIUM

Germanium (element 32), although far from being abundant in nature, could be recovered in rather large quantities in the form of its oxide, as a byproduct of zinc. It could also be recovered from various kinds of coal—an English coal, for example, is reported to yield an ash containing 1.6 percent GeO —and germanium sulphide might be obtained in considerable amounts from Bolivian tin-silver mines. Research has not yet found uses for this element, although it may be employed for coating mirrors and in therapy for combating anemia. The metal is crystalline gray white and does not tarnish rapidly. Its chemical properties are intermediate between those of silicon and tin. Germanium (99 percent) can be bought for \$5.50 a gram and the oxide (99 percent) for \$3.50 a gram.⁹

HAFNIUM

Although hafnium (element 72) appears to be one of the more abundant of the recently discovered elements, and consequently has commanded much scientific attention, as yet the only demand seems to have come from scientists who have investigated its properties or from radio-research laboratories. Hafnium occurs in minor amounts with its sister element, zirconium, which it resembles in many respects and from which it is separable only with great difficulty. The metal has a high electronic emissivity and a high melting point, probably over $2,200^{\circ}\text{C}$., higher even than most of the platinum metals. Ores carrying about 3 percent hafnia have been offered at 50 cents a pound, and hafnium oxide and chloride have been obtainable at approximately \$25 a gram, but these prices are nominal in the absence of any real business. Specimens of the metal can be purchased for \$1.50 per milligram.

INDIUM

Indium (element 49), a soft silvery metal of the aluminum group, is another electrolytic zinc byproduct that could be obtained in fairly substantial quantities. At certain plants, as much as 1 pound of indium can be recovered for each ton of zinc produced. An imposing list of prospective uses has been investigated, but actual consumption seems to be small, although metallic indium may be used in silverware, in medicine, for alloys that melt in hot water, and possibly for sundry other minor uses. The metal (99.5 percent) could be bought for 40 cents a gram in a large quantity, but ordinarily \$1 a gram is asked.

LITHIUM

Lithium (element 3) is the lightest solid substance known, being only half as dense as water. At room temperatures it can be handled as easily as calcium, but it does react slowly with air (particularly with the nitrogen, if moisture is present) and is otherwise unsuited for engineering uses when unalloyed. Alloys of lithium and aluminum, lead, zinc, and probably magnesium appear to be of value in engineering,¹⁰ and lithium may be used as a scavenging agent for iron, copper, nickel, and their alloys. Lithium-copper and lithium-treated conductivity

⁹ Quotations furnished by A. D. Mackay, New York, N. Y.

¹⁰ Osborn, H., Lithium, Theoretical Studies and Practical Applications: Electrochem. Soc., 1935, 68 pp.

bronzes are now produced on a fairly large scale, and for a number of years there has been a steady output of lithium-hardened bearing-metal alloys. The therapeutic properties of lithium salts were utilized generations ago; "lithiated" mineral waters still account for a substantial consumption of lithium chloride, while citrate and salicylate are still prescribed as remedies for rheumatism. Of outstanding interest, however, is the fast-growing use of lithium chloride for air-conditioning. Lithium metal costs as much as \$20 a pound, but lithium chloride (97 percent) was quoted at the close of 1936 at \$1.85 a pound and costs only \$1.40 a pound in ton lots,¹¹ and the carbonate (98 percent) was offered at \$1.25 to \$1.30 a pound and the fluoride at \$2 to \$2.50 a pound, all packed in barrels.

MASURIUM

Two elements of the manganese family long escaped detection. Some years ago they were described inferentially as eka-manganese and dvi-manganese, and their properties were forecast fairly accurately; but it remained for Noddack and Tacke (later Frau Noddack) in 1925 to find these elements, which they named masurium (element 43) and rhenium (element 75), respectively. The Noddacks and others have charted the spectrum lines of the telltale flame of masurium, but even so it is merely a name, and the nearest approach to commercial development has been the offering by rare-mineral dealers of specimens of molybdenite that may betray traces of its presence in the spectrograph.

POLONIUM

Polonium, or radium F (element 84), was the first radioactive element discovered by Madame Curie in 1898. It is near the end of the uranium-radium series and, being relatively short-lived (half life, 140 days) and soon changing to inert lead, has little commercial significance. Nevertheless, it is of sufficient scientific interest to justify the recent publication of a 29-page monograph.¹² Aside from valuable applications in nuclear physics, polonium is used at times in physiological research. It may be recovered from radium-lead residues and old radium ampules.

POTASSIUM

Potassium compounds are well known, and potash is one of the three principal plant foods. The metal (element 19) was the first to be isolated from an oxide by electric current. Although Davey made it in this fashion as early as 1807, potassium metal has never had real commercial significance, inasmuch as it costs more per pound and for almost every purpose is less efficient than sodium. A sodium potassium alloy exists as a liquid at ordinary temperatures, and a procedure has been perfected for making it. Domestic consumption at present probably does not exceed about 50 pounds a year, all of which comes from Germany. In lots of over 10 pounds the price (as reported by Charles Hardy, Inc., New York, N. Y.) is \$12.50 to \$14 a pound.

¹¹ Quotation furnished by Foote Mineral Co., Inc., Philadelphia, Pa.

¹² Haassinsky, M., *Electrochemistry of Polonium*: Trans. Electrochem. Soc., vol. 70, 1936, pp. 343-371.

RADIUM

By far the best known of the series of radioactive elements resulting from the disintegration of uranium is element 88 radium. It is widely used in therapeutics, chiefly for treatment of cancer. Smaller amounts are used industrially, principally as the activating agent for luminous paints used on watch dials, electric switch buttons, compasses, and elsewhere. More recently it has come to be used for radiograph testing of metal objects; this technique permits discovery of incipient weakness in large castings or forgings and supplements X-ray examinations. Formerly, radium appeared on the market generally as the bromide, packed in small, sealed, glass tubes or ampules; but nowadays radium sulphate is the usual compound, and it is packed in metal needles or tubes (about 1.7 mm in diameter) generally platinum. An outer case of lead is customarily employed to decrease danger of handling. The soluble salts, notably the bromide but also a little chloride, are sold only for emanation (radon) plants. The metal, which resembles barium in its general properties, was isolated by Madame Curie and a coworker in 1911, but it has not come upon the market.

Radium has been acclaimed as one of the most effective contributions of science toward alleviating human misery, but probably not more than about 26 ounces have so far been produced in the entire world. Roughly, half of this output has come from the Belgian Congo. Second in point of production is the United States, which produced the most radium from 1913 to 1922, when the richer and larger deposits of the Belgian Congo became productive. Almost no radium has been produced in this country since 1923. After that year the United States, although still the world's largest consumer, has met its needs by importations. A little carnotite is mined in Utah and Colorado, but it has been used as a source of uranium compounds, for radioactive drinking water and other therapeutic purposes, and as an experimental fertilizer for citrus crops. Considerable doubt has been expressed as to the real value of these radioactive preparations either medicinally or for stimulating plant growth, and production for these uses accordingly has been somewhat sporadic. On the other hand, the growing demand for uranium salts recently has stimulated greater activity in the Utah-Colorado area, where vanadium production has been resumed in well-organized fashion. These developments are discussed in greater detail in the chapter of Minerals Yearbook on Vanadium. The U. S. Vanadium Corporation, which during 1936 completed a 100-ton mill for treating carnotite, may also produce uranium or radium.

Czechoslovakia pioneered in the production of radium, which is recovered under Government auspices at Joachimsthal from ores won from the same deposits whence came the pitchblende that Madame Curie employed in all her early work. The Czechoslovakia industry, however, has never been large. England (Cornwall), Australia, and several European countries have contributed small amounts of radium ores, but never in significant quantities, and at present Canada is the only important source of radium outside of the Belgian-controlled African supply.

As reported in former volumes of Minerals Yearbook, an important discovery of pitchblende was made at Echo Bay, Great Bear Lake, Northwest Territory, by Gilbert LaBine late in 1930. In January 1933 Eldorado Gold Mines, Ltd., completed and placed in operation

its radium-refining plant at Port Hope, Ont. In summer the ores are transported to railhead at Waterways, northern Alberta, by water, a total distance of 1,400 miles. Some ore has been transported by airplane, air communication being maintained throughout the year. A little pitchblende has been found at other properties on Great Bear Lake, but no commercial production has been reported anywhere in that region except from LaBine Point, where underground development to a depth of 500 feet is reported to have disclosed highly satisfactory reserves of pitchblende accompanied by much silver. Shipments in 1936 exceeded those in the previous year, amounting to around 400 tons, and toward the end of the year the refinery treated an average of 20 tons of ore monthly, the normal yield being 1 gram of radium for each 10 tons of concentrated ore treated. Plant expansion was begun so as to increase capacity to 35 tons of ore per month, equivalent to a monthly recovery of over 3 grams of the element in the form of commercial salts. The uranium products, chiefly sodium uranate for the ceramic trade, which are jointly produced at the refinery, have found a ready market. Pitchblende occurrences have been reported in other parts of Canada, and active development has been maintained for several years by the Canada Radium Mines, Ltd., at its radium-bearing deposit at Cheddar, Haliburton County, Ontario, although no ore shipments have yet been reported from any of these localities. The total radium production of Canada previous to November 16, 1936, has been unofficially estimated at 1 ounce. Under the proposed production schedule it should amount to 2 ounces a year.

The price of radium, which in 1904 ranged from \$10 to \$25 a milligram, rose to \$125 and even \$135 during the World War and remained around \$100 until it was cut to \$70 in 1923, thereby causing production from American carnotite to cease abruptly. Soon after 1929 the collapse of world buying power resulted in a drop to \$50 a milligram, the nominal quotation remaining at this level until early in 1936, when it was lowered to \$40. During the last several years, sales of new radium actually have been made at \$35 and more recently at \$30; at forced sales, such as one required to settle a doctor's estate, radium has been bought for as low as \$20 a milligram. The 1.7-mm platinum needle container costs \$8, and its cost is added to the price of the radium unless the purchase amounts to 10 mg or more. Radon, or radium emanation, ordinarily is sold in the form of gold implants or "seeds", 5 to 7 mm long and 0.5 mm in diameter. The typical price of these implants in New York has been reduced from \$4 to \$2.50 per millicurie activity. Tubes having an initial activity of about 50 millicuries may be rented for about \$25 to \$35 per 48 hours; the radon content alone, exclusive of the gold tube, can be purchased outright for \$50.

Imports of radium salts into the United States reached a maximum of 21.97 grams valued at \$1,082,462 in 1934, dropped to 11.41 grams valued at \$525,807 in 1935, and increased to 17.04 grams valued at \$700,019 in 1936. Sporadic imports of "radioactive substitutes" are also reported in some years, reaching a maximum value of \$2,913 in 1928. Imports of uranium oxide and salts, byproducts of radium, are summarized in this chapter in the section on uranium.

RARE EARTHS

Sparking flints for pocket cigarette lighters represent almost the only use of the rare earths that is even moderately well known, and even in this guise the identity of the active elements—chiefly cerium, lanthanum, neodymium, and praseodymium—is obscured by the practice of describing the pyrophoric alloy as “misch metal” or simply “sparking metal.” For this purpose, as well as for flaming arc carbons and for preserving textiles, there is no need to separate individual members of this curiously homogeneous family, which includes 15 recognized elements (57 to 71). In making optical and art glass, however, such a separation is necessary; moreover, in making incandescent gas mantles a small amount of cerium oxide is extracted from the monazite along with the thoria, leaving a residue which represents the chief commercial source of the rare-earth group metals. Scandium (element 21) and yttrium (element 39) are not in the rare-earth group but are linked almost inseparably with that group by association in nature and general properties. Various practical applications have been found for many of these metals or their salts, but, even so, most of the rare earths must be listed as scientific curiosities. However, if more uses were developed, there should be no difficulty in obtaining adequate supplies, because they are actually fairly abundant in nature. Hopkins,¹³ the discoverer of illinium and a recognized authority, declares that there is probably more cerium in the world than there is tin, mercury, antimony, silver, or gold, and that the probable supply of the group as a whole is greater than that of zinc, lead, or several other fairly common metals.

Sparking flints are fairly expensive, due to the high cost of adding iron to the rare-earth alloy as well as to the difficulty in fabricating them. Losses are such that virtually 1 pound of misch metal is required to make 1 pound of ferrocerium. Both misch metal and ferrocerium cost \$6 to \$10 a pound, depending upon quantity, but pure cerium metal is worth \$25 a pound. Misch-metal prices are lower abroad than in this country. Almost the only rare-earth compounds for which general quotations are available are cerium hydrate and oxalate; at the close of 1936 the former was quoted at 65 cents and the latter at 28 cents a pound. Additional quotations, for small lots, furnished by A. D. Mackay (198 Broadway, New York, N. Y.), follow: Cerium oxide, technical, 75 cents a pound; cerium oxide, C. P., \$3.50 a pound; cerium nitrate, \$3.50 a pound; lanthanum metal (99 percent), \$2.50 a gram; lanthanum nitrate, \$20 a pound; lanthanum chloride, \$25 a pound; neodymium oxalate (for ceramic use), \$2.50 a pound; samarium nitrate, \$2.50 a gram; samarium chloride, \$2.50 a gram.

Misch metal is made in the United States by only one company, the American Treibach Co. (522 5th Ave., New York, N. Y.), which is affiliated with an Austrian company of similar name. Domestic consumption is of the order of 18,000 to 20,000 pounds a year, but could be increased quickly to several times this quantity. The company plant, at Niagara Falls, N. Y., now operates only 2 or 3 months each year, and salaries, power costs, and other overhead items have to be carried on a relatively small fraction of full-time capacity. If a customer could take as much as 100,000 pounds

¹³ Hopkins, B. S., *Europium, A Rare Member of the Rare-Earth Group*: Amer. Electrochem. Soc., vol. 66, 1936, Preprint 66-16, pp. 167-168.

annually, a price of \$2 a pound probably could be negotiated. So long as 99 percent of the material is made into ferrocerium for sparking flints for pocket cigar lighters and gas lighters such rapid expansion in consumption is not anticipated, but a good deal of experimenting is going on to develop other uses. Already a small outlet exists for fine steel making.

Misch metal can be made directly from monazite, but there is no occasion for using any virgin material as long as residues from gas-mantle manufacture continue to exist in great abundance. The making of gas mantles formerly was a comparatively larger industry in Austria, Germany, France, and a number of other European countries, as well as in the United States. At present, only 7,000,000 or 8,000,000 mantles are made in this country annually, compared with perhaps 60,000,000 immediately before the World War, and in Europe the output has diminished relatively even more. However, the accumulated residues at various plants here and abroad are said to be large enough to provide raw material for sparking flints at the present rate for about 75 years.

Imports of ferrocerium and other cerium alloys into the United States in 1936 amounted to only 22 pounds valued at \$117; less than 1 pound of cerium metal (value only \$19) was reported, and no imports of cerium ores (other than monazite) were recorded.

RHENIUM

Rhenium (element 75), discovered by the Noddacks in 1925 jointly with masurium, has been the subject of hundreds of scientific articles. Unlike masurium, rhenium seems available in fairly sizable quantities, for an ultrarare element, and it has been commercially available in pound lots since 1930. Progressive price reductions have stimulated a continuing interest, and an impressive list of patents indicates that the metal or its compounds may soon be commercially important. It has useful properties as a catalyzer and for thermo-elements, may be alloyed with rare metals, can be plated, and may have possibilities in incandescent-lamp technology. An important and unusual property is resistance to hydrochloric acid, a property that is retained in the plate. By 1935, production of rhenium had risen to a rate of 150 kg annually. The copper-bearing slates of Mansfield, Germany, contain 1 part in 5 million of rhenium, and the element is readily concentrated along with molybdenum and other rare elements in residues from the copper-extraction processes. If sufficient demand develops, other sources could be drawn upon to furnish as much as a ton or two a year. Perrhenate of potassium, the commercially available salt, is nominally worth about \$1.75 a gram but can be bought in quantities at \$1 a gram. Rhenium-metal powder is offered at as low as \$1.25 to \$1.50 a gram.¹⁴

RUBIDIUM

As indicated by its place in the periodic system, rubidium (element 37) is intermediate in its properties between caesium and potassium. Like caesium, it has been used in photoelectric cells. Rubidium salts are scientifically important as reagents in microchemistry and also have been advocated to modify the ghastly light from mercury

¹⁴ Quotations furnished by Charles Hardy, Inc., New York, N. Y.

vapor lamps. Although no known mineral contains a large percentage of rubidium, the element frequently accompanies other alkali-group elements in nature and occurs in the water of many springs. Lepidolite is the present commercial source, except in the U. S. S. R. (Russia), where it is obtained along with caesium as a byproduct from the Solikamsk potash deposits (carnallite). The metal is worth about \$6 a gram (in sealed tubes, in vacuo), and rubidium chloride, sulphate, or nitrate sells for 35 to 50 cents a gram, depending upon quantity. Fansteel Metallurgical Corporation and Calirare Chemical Corporation are domestic producers, and occasional importations are made. No data are available as to extent of domestic or foreign consumption, except that it is growing.

SCANDIUM

Although not a member of the rare-earth group, scandium (element 21) is present in many rare-earth minerals and resembles the rare-earth metals in certain analytical characteristics. There was no record of the metal having been isolated, even in a laboratory, until 1936, when German scientists were credited with having produced an appreciable quantity of metal of 94-percent purity.¹⁵ No commercial uses for its salts are known. Scandium oxide (Sc_2O_3), a white powder resembling magnesia, can be bought for scientific or educational use at \$7 a gram, while scandium nitrate costs even less, \$3.50 a gram.¹⁶

SELENIUM

The progress of selenium (element 34), from a copper-refinery waste to a widely used commercial product has been followed in some detail in Bureau of Mines annual reviews. Production in 1936 increased, due to the revival of copper refining, and a surplus is indicated, allaying previous fears as to prospects of early shortage. However, the demand for selenium keeps growing. The pigments field seems to be especially promising, at the moment, and consumption of selenium in the manufacture of paint would doubtless increase even faster were it not that the selenium pigments also contain cadmium, the supply of which has become quite scanty.

Domestic sales of selenium reached a peak of 362,697 pounds in 1928, having grown rapidly and fairly steadily from 123,565 pounds in 1922. Domestic production declined sharply during the depression, but imports more than made up the difference. Moreover, although statistics are lacking, there is reason to believe that most of the domestic output during the last 5 years was retained for home consumption, whereas formerly substantial exports were made.

Selenium and selenium salts imported for consumption in the United States, 1932-36

Year	Pounds	Value	Year	Pounds	Value
1932.....	1,914	\$2,240	1935.....	179,331	\$322,332
1933.....	1,855	2,402	1936.....	122,806	215,835

¹⁵ Metal Bulletin (London); No. 2106, July 14, 1936, p. 16.

¹⁶ Quotations furnished by A. D. Mackay, New York, N. Y.

Glassmaking was one of the first and is still a leading commercial outlet for selenium. Railway red signal glasses and other ruby glasses owe their color to selenium; but selenium is used more extensively in clear glass, having widely displaced manganese as "the glassmakers' soap" for neutralizing color. Long of scientific interest, though never of much significance as a sales outlet, are the several types of selenium cells that depend for their action upon selenium's peculiar property of increasing its electro-conductivity proportionately with the amount of light that falls upon it. By this means the lights of navigation buoys may be switched on at dusk and off again at dawn. The "optophone", which enables the blind to read ordinary type by ear, television operation, and sundry other devices¹⁷ can be operated on this principle. Of importance, also, is the use of selenium in the manufacture of rubber, and selenium compounds are used extensively as insecticides and for treating bulbs before planting. Steel making has begun to take quite a substantial quantity of the metal in the form of ferroselenium, used to make stainless steel machineable. Many miscellaneous uses may be mentioned—"flameproofing" electric cables, biological chemistry, rectifiers for various electrical devices, catalysts for sundry reactions, in medicine, and for protecting metals from corrosion. Cadmium-red pigments (made from cadmium sulphide and selenium) already account for a substantial consumption of selenium.

The New York quotation for selenium (black, powdered, 99.5 percent pure), previously held nominally at \$2 a pound, was quoted throughout 1936 at \$1.75 to \$2 a pound, according to quantity; ferroselenium (50 percent) was offered at \$1.90 a pound of contained selenium. London quotations were strictly nominal at the beginning of 1936, eased to 7s. 6d. to 8s. (\$1.88 to \$2) in February as supplies began coming on the market again, and later found their level at 7s. (\$1.75), ex-warehouse.

SODIUM

Common salt is the best-known sodium compound, but other sodium salts are highly important, and the metal itself (element 11), is far more important as regards tonnage made and used in the United States than are many better-known metals. Volume for volume, the world output of sodium exceeds that of nickel.¹⁸ It is a silvery-white, soft, ductile, malleable metal that melts a trifle below the boiling point of water (at 97.6° C.); the specific gravity is 0.9712, not quite as heavy as water. Sodium is an excellent conductor of electricity and, properly protected, may be used for this purpose; but it tarnishes instantly in the air, and if moisture is present the outside film fails to protect the metal underneath. Because it is so reactive chemically, sodium is used almost exclusively as a reducing agent in organic-chemical industries. The metal is made in the United States by only one company, the Roessler & Hasslacher Chemical Co. (Inc.), a du Pont subsidiary, from caustic soda. A new process, which has reached the pilot-plant stage,¹⁹ makes it by evaporating the mercury from sodium amalgam, which is an intermediate step in the Castner (electrolytic) process for making caustic soda.

Domestic production has been estimated at 8,000 to 10,000 tons annually for use mainly in making tetraethyl lead antiknock com-

¹⁹ Fink, C. G., *Work cited*.

pounds and in making synthetic indigo, consumption being almost equally divided between these two industries. Probably 5,000 tons more a year are made as an intermediate product in the manufacture of sodium cyanamide, but this is a continuous process, and the metal never gets outside of the plant. It has been imported from Germany and Norway, but only intermittently.

Prices are largely contractual, much of the consumption being taken by concerns financially affiliated with the manufacturer. By January 1929 the price had gradually receded to 15 cents a pound for contract shipments, but small quantities cost a great deal more; orders for carload shipments might be accepted at 19 cents, although at least 75 cents a pound is asked by chemical-laboratory supply houses. A recent innovation is shipment in 40-ton tank cars. Previously the metal was always shipped in sealed drums, although it was made to flow around the plant in heated pipes.

STRONTIUM

Celestite and strontianite, the leading strontium minerals, are discussed in Minerals Yearbook in the chapter on Minor Nonmetals. Strontium (element 38) is a member of the alkaline-earth group; and, as might be expected from its position in the Periodic System, the metal has properties intermediate between those of barium and calcium. Inasmuch as it necessarily costs a great deal more than either of these sister metals, it has found almost no real commercial use. Although it was placed on the market in 1932 at \$35 a pound and the price was later reduced to \$20 a pound, the metal is virtually a laboratory curiosity. In 1936, however, mention was made of an alloy of magnesium plus 35 to 50 percent strontium as a "clean-up" agent for high-vacuum thermionic tubes.²⁰ Strontium salts, notably the nitrate, are used in the United States almost entirely in pyrotechnics, the chief outlet being the red flares used by railway companies and, more recently, on highways as warning signals. Strontium salts are used in sugar refining in Germany but not in the United States. Employment of strontium carbonate or other compounds in the steel industry has been investigated and appears to have some possibilities.

TANTALUM

Tantalum (element 73) is rarer than gold in the earth's crust. Discovered in 1802, it remained a laboratory curiosity for over a century. For a relatively few years, 1903 to 1911, it was used for incandescent electric-light bulb filaments, only to be displaced for this purpose by tungsten. By virtue of its electrolytic valve action, tantalum found another temporary place in industry for charging storage batteries in the early days of the radio, and before the use of tantalum chargers was diminished too greatly, the manufacture of tantalum was well begun in the United States. The American producer, Fansteel Metallurgical Corporation of North Chicago, Ill., rapidly created new uses, so that the metal is firmly established in a variety of practical applications. An outstanding characteristic of the metal is its remarkable resistance to acid corrosion. Being at the same time weldable and readily fabricated into almost any desired

* Fink, C. G., *Rare Metals and Minerals: Min. and Met.*, vol. 18, no. 361, 1937, p. 24.

shape, it finds a substantial use in chemical process equipment and rayon spinnerets. In electronic tubes, tantalum is used for anodes or plates (in which, due to its gas absorptive capacity, it acts as its own getter and keeper), and tantalum support rods, getter cups, filaments, and grids are widely used. Due to its hardness and high melting point, tantalum carbide is a constituent of hard cutting-tool mixtures, notably Vascology-Ramet, and forms an important outlet for the metal. Other uses of tantalum have been mentioned in previous chapters of this series, and a résumé of late developments will be found in a paper by Balke,²¹ the senior investigator in this field.

World supplies of tantalum ore have come almost exclusively from the remote Pilbarra district, Australia. Domestic ores have mostly carried too much columbium or have been otherwise too low-grade to be used for making tantalum metal, although exported for use in making alloys. Only small shipments have been made from Africa, South America, and British India. In 1936, the Soviet authorities announced that tantalum had been discovered in the ores of the Selianka titanium mine in quantities to justify the expectation that the U. S. S. R. (Russia) might soon become an exporter.

Detailed production figures for tantalite usually are not recorded, but a recent official British review²² shows for 1935 an estimate of 16,800 pounds for the Western Australian output of tantalite (compared with 26,900 pounds in 1931). Nineteen thousand five hundred and seventy-two pounds of tantalite and columbite in Union of South Africa (a new producer), and 13,448 pounds of tantalite from South-West Africa, which came into commercial production in 1934 with 661 pounds. The South African material consists largely of tantalite and is obtained principally by the African Mining & Trust Co. (Pty.), Ltd., from weathered pegmatite in the Pietersburg district of the Transvaal.

Imports of tantalum ores into the United States in 1936 aggregated 20,758 pounds valued at \$30,751, chiefly from Australia (14,246 pounds) but including 2,032 pounds from the Netherlands and 4,480 pounds from British East Africa.

Prices of tantalum have been stable in recent years, no attempt being made to keep pace with the fluctuations of the platinum market. For domestic consumption the base price for C. P. rod has remained for some time at \$160.60 per kilogram and for sheet at \$143 per kilogram. Discounts are allowed for volume business. London quotations remained nominal at £17 10s. to £18 10s a pound, equivalent to around \$180 a kilogram.

TELLURIUM

Tellurium (element 52), like selenium, is a member of the sulphur family and, again like selenium, is a byproduct of electrolytic copper refining and can be recovered from other operations that treat sulphides. For example, at Odessa, U. S. S. R. (Russia), it occurs in flue dusts from a superphosphate plant. For many years no uses could be found for tellurium; in fact, it long remained an altogether obnoxious element that plagued the metallurgist in various ways. For a time it was thought to have a place in antiknock compounds for gasoline, but its nauseating odor, among other things, was objection-

²¹ Balke, C. W., *Columbium and Tantalum: Ind. and Eng. Chem. (Ind. Ed.)*, vol. 27, no. 10, 1935, pp. 1166-1169.

²² Imperial Institute (London), *Production, Utilisation, and Marketing of Columbite-Tantalite Minerals: Bull.*, vol. 34, no. 3, 1936, pp. 348-353.

able. The first use of real importance was the discovery by U. C. Tainton that tellurium was a most valuable reagent for purifying zinc solutions at western electrolytic plants, and by 1930 this provided an important outlet. The quantity required is 13 pounds per ton of zinc. By 1932, serious attention was being given to the successful use of tellurium as a rubber-compounding material. It increases the resistance of rubber to heat, seems to be effective in revitalizing old rubber, and improves ageing qualities. Gradually it came to be used commercially in rubber hose and cable coverings where great toughness and abrasion resistance are required. A new use in the rubber industry is in making latex. Another relatively large outlet for tellurium is for hardening lead. An alloy containing 0.06 percent tellurium was placed on the British market in the early 1930s; later it was made in the United States under the trade name "Teledium." Patent rights cover a wide range of lead-base alloys with varying quantities of tellurium and other metals, such as cadmium, antimony, and tin. The material is almost twice as strong as pure lead and has 8 to 12 times the corrosion resistance, although it can be worked very much like ordinary lead. Important, too, may be the use of tellurium in the steel industry. Although its use in steel is just beginning, laboratory tests seem to indicate that tellurium is better than selenium because it is more easily soluble in the steel. Difficulty has been experienced, however, in getting a suitable low-grade alloy. A ferrotellurium containing even as low as 9 percent does not seem to work well, and a 2-percent alloy is desired. The use of tellurium ("metalloid of the selenium-tellurium group") is covered by Carpenter Steel Co. patents for free-machining steels (U. S. Patents 2009713-16). Colloidal tellurium has been introduced in medicine, and the element and its compounds are listed as bactericides. In conjunction with ferric chloride, telluric anhydride has been used in light-sensitive photographic preparations.

Three American companies reported production of tellurium in 1936, and a fourth reported sales from stock. American tellurium is exported to Europe, although Germany, Sweden, and possibly other countries likewise are recovering tellurium. In Canada, tellurium is now being produced at Copper Cliff, Ontario, and at Montreal East, Quebec, the total output amounting to 52,724 pounds valued at \$93,322 in 1936, compared with 16,425 pounds valued at \$32,850 in 1935.

With the upturn in copper refining there is no early prospect of a shortage of tellurium, but in 1935 inquiry was made as to additional supplies of metallurgical residues and even as to deposits of tellurium-bearing ores. An occurrence of native tellurium associated with more or less gold has been investigated in Catron County, N. Mex., which seems to be the only domestic occurrence of even potential importance.

The New York quotations for tellurium have continued nominally unchanged for several years at \$2 a pound. In London, trade journals were quoting the metal at 6s. 6d. to 7s. 6d. (\$1.60 to \$1.85) in January 1936. Later this quotation was narrowed to 7s. (\$1.75).

THALLIUM

A bluish-white, soft metal, thallium (element 81) resembles lead not only in its physical properties but also, to a considerable extent, in its chemical properties, although in the latter respect it somewhat resembles potassium. The metal itself is obtainable without much difficulty, but it is used only in quite small amounts for special alloys; lead-thallium alloys are highly resistant to corrosion. Even in its compounds thallium finds no very large sale, although significant quantities, chiefly as sulphate, are used in rat poisons and for ground-squirrel and rodent control generally. It also has been recommended for killing ants and as a fungicide and insecticide. Small quantities, a few hundred pounds annually, have long been used in optical glass, photoelectric cells, and medicine, and later developments are moth-proofing agents and fabric-finishing materials. A variety of other uses, including antiknock motor fuel, have been suggested, many of them having been patented, but none of them seem to have reached the commercial stage. Formerly, thallium was used rather widely in depilatories, but inasmuch as it is a cumulative poison of high toxicity this use has been discouraged. Recently, however, experiments have been made in the U. S. S. R. (Russia) with a view to controlling the moulting of sheep, particularly of merinos that do not moult naturally; promising results were obtained, although many of the sheep died, and more work has to be done.

Thallium is not a common element, but it is present in a large number of minerals and moderately substantial quantities may be recovered from the flue dusts from lead furnaces and pyrites burners. Partly because the demand is rather small there is only one domestic producer, the American Smelting & Refining Co.; but additional quantities of thallium sulphate and a little thallium acetate have been imported from Germany, Poland, and Belgium. Prices since the World War have ranged from above \$20 to a minimum of about \$5 a pound. The price of the metal in small lots is \$15 a pound.

THORIUM (AND MESOTHORIUM)

Thorium (element 90), like uranium, is the source of a series of radioactive elements of lower atomic weight. In the process of disintegrating to inert lead, the thorium group emits radiations similar to but not always identical with those from radium. Mesothorium, the immediate disintegration product of thorium, is chemically identical with radium. Its preparations emit the three types of rays characteristic of radium, but it is much shorter lived. Separated from thorium, a given specimen of mesothorium decays to half value in 6.7 years, to one-fourth of its original value in another 6.7 years, to only one-eighth of its original value in a third period of 6.7 years, and so on. The half-life period of radium, on the other hand, is 1,690 years. Mesothorium can be substituted for radium for certain therapeutic purposes but is possibly more important commercially in radioactive luminous materials. Over a period of 15 years, the brightness of luminous materials activated with mesothorium is in no way inferior to that of those made luminous by radium.²³ Formerly radium cost a great deal more than mesothorium, but as radium has

²³ Schlundt, Herman, *Mesothorium: Foote-Prints*, vol. 4, no. 1, 1931, pp. 3-17.

become cheaper, mesothorium, remaining at about a constant price, is the more costly of the two. In 1936, the American Treibach Co. (522 Fifth Ave., New York, N. Y.) imported 45 to 50 mg of mesothorium from Austria. Domestic requirements may increase, but at present more mesothorium is used abroad than in the United States. In England and France, for example, luminous telephone dials are employed, activated with mesothorium.

The main use of thorium has been in incandescent gas mantles, for which purpose thorium nitrate is extracted from monazite sand along with a small amount of cerium. The fabric is saturated with a mixture of "rare-earth nitrates", accompanied by beryllium nitrate and magnesium nitrate, and then burned. Mesothorium is a byproduct of the production of thorium nitrate, though not always recovered. Thorium compounds are used in X-ray work, and thoria catalysts have been employed for certain reactions. Thorium oxide is a super-refractory and has been used recently to an increasing extent in making laboratory crucibles that can be employed in melting pure metals at temperatures up to 2,300° C. Sintered thorium metal was put on the market by Westinghouse Lamp Co. laboratories in 1930 in various shapes and sizes at \$75 a pound and more. Thorium has been used in filaments of tungsten lamps to prevent embrittlement; for this purpose, however, as well as for electron-discharge devices and other electron-emitting uses, the element is not introduced in the form of the metal. Suggested uses for the metal are in photoelectric cells, glow-tube electrodes, and X-ray targets.

Thorium is a soft, malleable metal, stable in the atmosphere and otherwise easily worked and handled. In addition to its high thermionic emissivity, consideration may be given to the fact that its oxide is the most refractory oxide known. It is not destined to be a cheap metal, but neither is it unduly costly now that the price of monazite has fallen as a result of the diminished demand from the gas-mantle industry for thorium nitrate. This combination of circumstances would seem to afford a sound basis for active research into new fields of use.

Thorium nitrate has recently been quoted by the Oil, Paint, and Drug Reporter at \$2.20 a pound. Monazite, the ore of thorium, was formerly quoted at \$60 a ton basis 6 percent ThO_2 , but more recently an 8-percent grade has been listed at \$60 to \$75 a ton. Mesothorium costs about \$35 a milligram.

The imports of thorium nitrate and other thorium compounds in 1936 amounted to only 4,411 pounds valued at \$5,578. In 1921 they were 44,554 pounds valued at \$89,672, and the maximum was 144,413 pounds valued at \$309,760 in 1914 (fiscal year).

TITANIUM

About two and a half times as plentiful in the earth's crust as carbon, titanium (element 22) is a constituent of almost all common rocks. Ilmenite and rutile, however, are the only minerals that have been mined at all extensively as titanium ores, and commercial deposits of these minerals are relatively few. Fortunately, ilmenite deposits in British India, Norway, and the United States are large and easily worked, so that the supply is abundant and cheap. Titanium metal has virtually no commercial uses, though it can be purchased at about \$6 a pound. Its alloys, particularly ferro-carbon-titanium, which is

used in the steel industry, are important and are consumed in rapidly growing quantities not only in steel making but also for use in making iron castings and various nonferrous alloys. Formerly employed almost exclusively as a deoxidizer, it has recently begun to be important in the manufacture of rustless steels to inhibit intergranular corrosion. Titanite, an aluminum-manganese-titanium alloy, takes a high polish that resists corrosion. Most important is the production of titanium pigments, which has grown at an astonishing rate in less than a decade from an insignificant industry requiring only 2,000 or 3,000 tons of ilmenite to a large business whose purchases of this raw material now exceed 100,000 tons a year. The consumption of rutile likewise has increased sharply. Scarcely 5 years ago this naturally occurring dioxide of titanium was used to only a small extent in the ceramic industry and had almost no other important applications until it began to be demanded in really large quantities for the manufacture of welding rods. Meanwhile, its ceramic uses have shown healthy growth. Titanium dioxide is used in ceramic glasses, in "topaz" yellow glassware, and to increase fluidity of acid-resisting enamels. For the acid-stable enamels as much as 8 percent TiO_2 is added, the yellow coloration being suppressed by a 2-percent addition of sodium fluosilicate.²⁴ A German patent (622346, I. G. Farbenindustrie) describes the production of a glass containing 20 to 48 percent of TiO_2 and 20 to 35 percent alkali (remainder acid oxides) made colorless by nitrate additions to the batch, which is melted slightly above $1,300^\circ\text{C}$.

Miscellaneous uses of titanium compounds are for smoke screens, "sky-writing", and pyrotechnics (tetrachloride); for arc-light electrodes; in dyeing and tanning; as abrasives (carbide); and in medicinal and toilet preparations. In addition to their use in paints and lacquers, titanium pigments are being used to an increasing extent in paper, linoleum, for delustering rayon, in printing ink, white rubber, plastics, cosmetics, soaps, and in shoe polishes and various leather and synthetic finishes.

Summarizing 1936 developments, E. L. Lasier, vice president of the Titanium Alloy Manufacturing Co., in a letter to the author, comments upon the greatly increased use of iron-titanium alloys (both high and medium carbon) in the steel industry for deep-stamping and automobile body stock. In the production of intermediate manganese steels, ferro-carbon-titanium is displacing more expensive alloys, notably nickel and vanadium. Other important developments have been the work on temper-hardening of copper-titanium alloys, the use of titanium in gray cast iron and in aluminum (through the use of a master aluminotitanium alloy), and a prospect of employing the element to assist in age-hardening of chrome-nickel steels.

The American Rutile Co., leading producer of rutile, formerly operated its milling plant at Roseland, Nelson County, Va., only 2 or 3 months at a time, but in 1935 it built a new, modern mill which was operated almost continuously in 1936 and may be enlarged to a capacity of 500 tons of crude ore a day. No production figures are released by the company, but private estimates place the present output as high as 2,000 short tons of rutile a year. Rutile or brookite was produced in Hot Springs County, Ark., in 1936 by the Titanium Corporation. It has been difficult to recover high-grade rutile in

²⁴ Vielhaber, Titanium Dioxide: *Emailwaren Ind.*, vol. 12, no. 52, 1935, pp. 419-420; *Ceram. Abs.*, vol. 15, no. 8, 1936, p. 231.

commercial quantities from this area, but the ore-testing section of the Bureau of Mines succeeded in making good-grade concentrates from Arkansas rutile by flotation.

Ilmenite produced in this country is largely a byproduct of rutile mining by the American Rutile Co., or a joint product of apatite by the Southern Mineral Products Co., Piney River, Va., which is not far from the Roseland operation although in Amherst County. In 1936 the latter company sold its adjoining chemical plant, used for making calcium monophosphate and titanium pigments, to the Virginia Chemical Co., a newly created subsidiary of the International Printing Ink Co. The original company, however, continued its mining activities and, in addition to supplying apatite and ilmenite concentrates to the new concern, shipped ilmenite concentrate to the ferro-alloy works of the parent company, the Vanadium Corporation of America, at Niagara Falls, N. Y.

Domestic production statistics cannot be published without disclosing the operations of individual companies, but the import statistics serve to show the rapid growth in domestic consumption of both ilmenite and rutile. For several years British India supplied all the imports of ilmenite and is still the principal supplier, but Norway contributed 22,472 long tons in 1935 and 32,126 tons in 1936 despite rumors to the effect that the Norwegian ore is not well liked in the United States and accordingly will henceforth be sold mostly in Europe. Of possible significance, too, is the average import valuation in 1936 of \$6.22 a long ton for imports from Norway, compared with \$5.32 for those from British India and only \$4.30 for the 8,600 long tons credited to the United Kingdom (obviously a reshipment).

Titanium ores imported for consumption in the United States, 1932-36

Year	Ilmenite		Rutile	
	Long tons	Value	Pounds	Value
1932.....	33,491	\$231,652	176,395	\$4,508
1933.....	38,610	196,211	157,658	3,737
1934.....	71,710	356,208	309,221	7,350
1935.....	115,871	656,293	423,577	13,124
1936.....	127,491	687,822	1,019,449	38,552

Data on imports by customs districts show that all Norwegian ilmenite is imported at New York, whereas Indian-ore imports are divided between Maryland and Philadelphia. In former years there were entries at New Orleans for shipment to St. Louis, but this movement ceased before 1936.

Rutile is now imported chiefly from Brazil, although small quantities were received in 1936 also from Canada (14,000 pounds valued at \$1,128) and Australia (10,000 pounds valued at \$674). About 75 percent of the rutile arrives at New York; the rest goes to Philadelphia, except that in 1936 a fair-sized shipment was made to Virginia.

Imports of ferrotitanium and other titanium alloys are quite small, amounting in 1936 to 2,240 pounds valued at \$303 from the United Kingdom.

Among foreign developments may be mentioned further prospecting at the Selianka mine in the Chelyabinsk oblast, U. S. S. R. (Russia), and a substantial increase of exports of "amang", a product of the

Straits Settlement containing only 0.15 percent tin and valuable chiefly for its titanium content. In Norway production has been increased so that around 60,000 tons annually can be handled, and a new aerial tram was built in 1936, according to a British report. At one time Ceylon produced monazite from its black-sand deposits, and recently the Ceylon Bureau of Industry and Commerce was reported to be giving attention to possible exploitation of these areas for ilmenite and zircon. The largest known black-sand deposit on the island is on the east coast about 35 miles north of Tricomalee and extends 4 miles along the shore. Brazil's rutile deposits are in the States of Goyaz and Minas Geraes. The ores from the latter State ordinarily contain ilmenite and, accordingly, analyze only 70 to 85 percent TiO_2 , but those from Goyaz run up to 95 percent or more. In 1936 quotations f. o. b. Rio de Janeiro, for export to United States and England, were as low as \$20 a metric ton. Ilmenite occurs in beach-sand deposits on the coast of Espiritu Santo, accompanied by monazite, zircon, garnet, and magnetite. The entire production of ilmenite in India comes from beach deposits leased from the Government of Travancore State. Until a few years ago two British firms, the Travancore Minerals Co., Ltd., and Hopkins & Williams, Ltd., were the only producers, but in 1932 F. X. Pereira & Sons entered the field, and, even more recently, M. E. Masillamany, B. A., Travancore, is rumored to have begun exporting, while a group called the Malabar Mining Co., Neyyattinkara, was said to be negotiating for a mining lease.

⁴ Concentrates.

Ferro-carbon-titanium, the leading tonnage alloy, was quoted in 1936 at \$137.50 per ton, f. o. b. Niagara Falls, N. Y., for the 7- to 8-percent-carbon product. Rutile concentrates, guaranteed minimum 94 percent, continued to be quoted at 10 cents a pound, although less than \$100 a ton could be obtained for lower-grade ore that required further cleaning before it could be sold for ceramic uses. The price of artificially produced titanium dioxide of pigment grade was reduced from 17 to 16 cents a pound on November 4, 1936. This quotation is for carload lots and for packing in paper bags; for material packed in barrels the quotation is 16¼ cents.

URANIUM

According to most chemists, uranium (element 92) is the heaviest element that is ever likely to be found in our universe. It spontaneously decomposes to form at least two families of radioactive elements (of progressively diminishing atomic weight), of which radium is the best-known and most important commercially. The ratio of radium to uranium in pitchblende and other ores never exceeds 1 part in 3.4 million, and unless the radium-bearing minerals are old enough to have reached equilibrium, the proportion is even less. It follows that all radium-recovery operations release at some time a fairly large quantity of uranium compounds. Occasionally there has been a surplus of such compounds, although, conversely, low-grade ores also have been utilized mainly as a source of uranium. The free element can be made without excessive difficulty in the form of black powder, but it has no recognized uses. Ferro-uranium has been advocated for use in making steel, and for a brief period after 1918 it was employed in a small way as a substitute for ferrovanadium; however, the consensus of opinion among steel metallurgists now seems to be that adding uranium to steel affords no improvement that cannot be obtained more economically by other means. Uranium acetate and other compounds are valuable analytical laboratory reagents, and uranium salts have been employed to some extent in photography, dye making, and medicine. The chief use of uranium, however, is in ceramic glazes and glass manufacture to produce a characteristic yellow colorization, for which purpose sodium uranate (Na_2UO_4) is the usual commercial vehicle. This salt is either yellow or orange, contains 83 percent U_3O_8 , and is worth about \$1.25 a pound.

The Vitro Manufacturing Co., Pittsburgh, Pa., and the Shattuck Chemical Co., of Denver, Colo., produce uranium compounds in this country from domestic carnotite ore. A substantial part of the domestic requirements, however, is satisfied by supplies from foreign sources. Imports of uranium oxide and salts were relatively small until about 1926, rose to 272,913 pounds valued at \$344,548 in 1929, and then, after declining during the depression years, jumped to 296,389 pounds valued at \$292,207 in 1935. In 1936 they rose further to 341,040 pounds valued at \$374,110; most of it was from Belgium, as in former years, although 62,567 pounds valued at \$61,088 came from the newly created Canadian source.

VIRGINIUM

The blank space in the periodic chart for "eka-caesium" (element 87) was filled, it was announced, in 1930 when Dr. Fred Allison and his coworkers at Alabama Polytechnic Institute declared that they had discovered this long-sought substance by their magneto-optic analysis of pollucite and lepidolite. They named it virginium (Vi). The validity of this discovery was challenged by Prof. Jacob Papish and Eugene Waiver, of Cornell University, who announced their own discovery of this element by X-ray analysis of a calcite crystal. Later, doubt arose in the Cornell laboratories as to whether the newly noted spectral lines exhibited by this crystal actually were due to this elusive element. In many minds, therefore, there is still a question as to whether element 87 has been discovered. The evidence certainly tends to show that this element is not present in perceptible

proportions in many substances on this earth. Even Dr. Allison found that the concentration of virginium in the substances he investigated was very low, ranging from a few parts in a million million to a maximum of 1 part in 10 billion. Notwithstanding its high atomic weight and its close proximity to radium in the periodic table, it appears likely that virginium is not radioactive.

YTTRIUM

Yttria was discovered by the distinguished Finnish scientist, Jacob Gadolin, in 1794, and half a century elapsed before Mosander showed that, instead of being a simple oxide, it contained at least three elements. Whereas the yttrium family comprises two subgroups of rare-earth metals, yttrium (element 39), according to modern terminology, paradoxically is not a member of the rare-earth group, although it would seem to belong there by virtue of almost every criterion except its order in the periodic arrangement of the elements according to their progressively increasing atomic weights. In common with rare earths, yttrium is commercially obtainable in gas-mantle residues, and yttrium nitrate can be extracted from monazite sands by nitric acid. However, monazite rarely contains as much as 5 percent yttria, and the Government mineralogist of Western Australia has reported that in 1920 as much as 1 ton of gadolinite carrying 45 percent yttrium earths and 4 percent cerium earths was exported from Cooglegong, and at various times some hundreds of pounds of yttriotantalite, tanteuxenite, and xenotime—all high-yttrium minerals—have been collected for experimental purposes. Yttria has been used in gas mantles and in arc-light electrodes, especially those for ultraviolet radiation. Several yttrium salts are employed in analytical chemistry and may have use as insecticides or for mothproofing (see United States Patent 1739840). The free element is produced without undue difficulty as a coarse gray powder and has been used in patented lamp alloys that exhibit selective radiation at luminous temperatures. Yttrium nitrate costs 20 cents a gram and the metal \$10 a gram, in small quantities.²⁵

ZIRCONIUM

During the last few years the consumption of zirconium compounds has grown rapidly. The element (40 in the periodic table), is marketed in metallic form, although not in large quantities. The powdered metal is used to a limited extent in flashlight mixtures and in ammunition primers; and pure, wrought, crystalline-metal wire is used in radio tubes and sheet metal in spinneret cups for rayon manufacture. Zirconium-silicon and zirconium-ferrosilicon are developing a gradually growing use in steel making, as superscavengers of oxygen and sulphur and for controlling grain size. The specific gravity of the metal is 6.52. Hence, it is a trifle lighter than antimony and considerably lighter than steel. Its melting point, 2,130° C., is higher even than that of platinum. Zirconium is a very reactive metal, although it is resistant to hydrochloric acid and nitric acid does not affect it at all. It combines with all except the rare gases, the compounds thus formed tending to migrate toward the inside of a filament, leaving a fresh surface exposed—an important factor in

²⁵ Quotations furnished by A. D. Mackay, New York, N. Y.

certain classes of high-temperature closed-tube applications. The extraordinary increase in industrial importance of zirconium, however, is based upon the employment of its compounds in enamels and for electrodes or welding-rod coatings. Properly purified zirconium oxide is quite as good an opacifier as tin oxide in virtually all types of commercial vitreous enamels and costs much less. Another important development is the fast-growing use of a new type of glaze, in which zirconium is introduced not only in the opacifier or pigment of the glaze but also to some extent into the frit or glass. It is claimed that this type of glaze is superior to other glazes in durability, stability of color, and economy. The indicated market is large, and sales of zirconium products for this purpose almost tripled in 1936. A particularly interesting development is the new electrical heating element for stoves and furnaces made with granular and milled zircon. Zirconia refractories are of some importance, and zirconium compounds have many minor uses, some of which, still in the development stage, may contribute further to the rapid increase in demand for this relatively new metal in the industrial field.

Zircon, the silicate ore of zirconium, has been produced sporadically in North Carolina and subsequently in Florida, chiefly as a by-product of the short-lived monazite industries of the South; but no domestic production of zirconium ores has been reported since 1927, when operations at Pablo Beach, Fla., yielded 3,646 short tons. Zircon and cyrtolite have been reported in Canadian pegmatites, but nowhere in North America has there been any substantial production of these ores. For many years Brazil was almost the only source of world supply, producing not only zircon from beach sands but also baddeleyite, a natural oxide. British India is another large producer, zircon accompanying the monazite and ilmenite in the Travancore beach sands, the proportions varying considerably, however, at different points along the coast. Among the newer producers is Australia, where zircon likewise is recovered from beach sands that extend discontinuously along the coast of New South Wales from Fort MacQuarie to the Queensland border. One of the operations in this area is financed by the Titanium Alloy Manufacturing Co., of Niagara Falls, N. Y.

Until about a dozen years ago, world consumption of zirconium ores probably never exceeded a very few hundred tons in any single year, and it was not until about 2 or 3 years ago that domestic needs exceeded about 500 tons annually. An importation of over 1,500 short tons of zirconium ore was reported for the period July to December, 1918, but apparently much of this went into stock, as did also some portion of the domestic production from Florida beach sands. Eventually these stocks were disposed of, and since about 1928 the import statistics doubtless indicate rather closely the quantities available for consumption in this country. In 1929 the imports jumped to 1,345 short tons, increasing to 1,519 tons in 1930 but dropping to 562 tons in 1931. Later figures are given in the following table, which shows also recent rather small importations of zirconium metal powder, ferro zirconium, and other alloys.

Zirconium ores and alloys imported for consumption in the United States, 1932-36

Year	Zirconium ores		Ferrozirconium, zirconium, and zirconium ferrosilicon	
	Pounds	Value	Pounds	Value
1932.....	26,506	\$437	-----	-----
1933.....	568,581	5,306	-----	-----
1934.....	1,706,192	27,197	112,000	\$7,605
1935.....	5,756,728	76,923	26,166	2,079
1936.....	11,565,340	115,180	86,872	4,797

Until 1935 ore was imported almost exclusively from Brazil, but increasing quantities have come from other sources. In 1936 British India supplied 1,422 tons, valued at \$29.35 per ton; Australia, 3,603 tons valued at \$15.35 per ton; and Brazil, 751 tons, valued at \$23.95 per ton. In addition, Canada furnished 6 tons and the United Kingdom 1 ton. A considerable portion of the imports from Australia comprised sands containing not more than about 60 percent zircon mixed with rutile and other minerals. Inasmuch as most of this material and possibly some portion of imports from other countries during the last 2 years has gone into stocks, the increase in the consumption of zircon, large though it is, is not so large as the remarkable increase in imports might indicate.

The Foote Mineral Co., Philadelphia, Pa., has recently quoted zirconium-metal powder (98 percent) at \$6.35 per pound in ton lots, crude zirconium oxide (80 percent) lump at \$80 per ton in carlots, and zirconium concentrates (62 percent) at \$46 per ton in carlots. Zirconium-metal sheet sells for about 30 cents a gram.

Part 1.—BITUMINOUS COAL ¹

By F. G. TRYON, L. MANN, and W. H. YOUNG

THE BITUMINOUS INDUSTRY IN 1936

In the bituminous-coal industry the year 1936 was one of expanding production but of intensified competition. Output increased to the highest level touched since 1930. Prices, however, declined slightly, or at best in most areas maintained the levels of 1935, although a 10-percent increase in wage rates had become effective in October of that year.

Final detailed reports of operation in 1936 will not be available for several months because of the time required to canvass the 6,500 commercial producers. Meanwhile, the broader trends are shown by preliminary or sample data presented in tables 1 to 7. The current

FIGURE 44.—Trends of production, stocks, and prices of bituminous coal, 1928-36.

indicators, drawn largely from railroad or trade-association sources, should be viewed against the complete and accurate record for the year 1935. Thus, the detailed tables for 1935 will serve as a background for the current changes of 1936.

Production.—The principal developments in 1936 are summarized in table 1. Production reached a total of 434,070,000 net tons, an increase of 61,697,000 tons (16.6 percent) over 1935. Compared with 1932—the trough of the great depression—the record for 1936 represents an increase of 124,000,000 tons. (See figs. 44, 45, and 47.)

Exports and imports.—Exports increased, but in a smaller ratio than production. Shipments to Canada and Mexico were 9,911,987 net tons—a gain of 9.6 percent. Exports overseas and to all other destinations increased 6.4 percent.² (See fig. 54.)

Imports also increased, but remained negligible in proportion to the domestic supply.

Changes in stocks.—Part of the increased demand in 1936 consisted of purchases for storage. Stocks in the hands of industrial consumers

¹ Data for 1936 are preliminary; detailed statistics with final revisions will be released later. Data for 1935 are final.

² Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

and retail coalyards increased from 37,017,000 tons at the beginning of the year to 43,499,000 at the end. The net addition to consumers' stocks was thus 6,482,000 tons during the year—an increase of 17.5 percent. In some instances, the flow into storage went to increase reserves in anticipation of a possible stoppage of production when the wage agreements should expire March 31, 1937. In general, however, the additions to stock piles were no more than were necessary to keep pace with the increase in consumption, and the reserve on hand January 1, 1937, was enough for 31.7 days compared with 30.2 days the year before. In terms of current requirements, the reserves at the beginning of 1937 were therefore far below those built up on some previous occasions, such as April 1, 1927, when a 53-day supply was in storage.

Stocks on the upper Lake docks increased by 12.1 percent during the year, or slightly less than the indicated increase in national consumption.

Coal in cars unbilled at the mines or in classification yards increased 2.2 percent in tonnage during the year but decreased in relation to demand. At the beginning of the year the unbilled loads were equivalent to 0.9 day production and at the end of the year to 0.8 day.

Consumption.—Allowing for foreign trade and for changes in consumers' stocks, the total consumption in the United States was 417,202,600 tons, an increase of 15.8 percent over the year 1935. The increase was widely distributed and was shared by nearly all of the major classes of consumers. (See table 5 and fig. 46.) By far the largest increase centered around the revival of activity in steel. Consumption of gas and steam coal at steel works and rolling mills increased 14.7 percent over 1935. Consumption in furnace byproduct coke ovens increased 38.1 percent and in beehive coke ovens 96.9 percent. The total increase in the consumption of the iron and steel industry was approximately 16,000,000 tons.

Gains in other channels of consumption, though less striking, were real. The demand for locomotive fuel increased 13.2 percent. Rapid expansion in sales of electric power, coinciding with the low heads of water at some hydroelectric plants affected by the drought, brought an increase of 20.6 percent in the coal requirements of the electric power utilities.

Consumption at cement mills advanced 38.3 percent and at general manufacturing plants 18.6 percent. Even the trade in coal for ships' bunkers, which had largely passed to fuel oil, increased 3.4 percent during 1936.

Price trends.—Prices stiffened in the cold weather of January and February but declined over the rest of the year. Trade-journal quotations on 61 grades of coal averaged \$2.26 a ton, f. o. b. mines, in February 1936 as against \$2.04 in the same month of the year before. Thereafter in each month from April to December 1936 the average quotations on the same coals ran somewhat below those of the corresponding month of 1935. The average of the quotations for the entire year 1936 is \$1.99 a ton, as against \$2.04 in 1935—a decrease of 5 cents.

Other barometers likewise point to stationary or often declining prices. The average cost of railroad fuel, excluding direct freight charges, was \$1.89 a ton in 1936—exactly the same figure as the year before. The average price paid by Canadian buyers for American

coal, f. o. b. mines in the States, declined 6 cents a ton.³ Cost of coking coal delivered at merchant byproduct ovens declined 13 cents a ton. Costs of bunker coal delivered to vessels in foreign trade declined 6 cents a ton. The average value of all coal exported from the United States, reckoned at the port of loading, increased over 1935, but this increase was only 6 mills per ton.

The only barometer pointing definitely to an increase was the average retail price in 38 of the principal cities. This price advanced 10 cents a ton (1.2 percent) from an average of about \$8.30 a ton in 1935 to about \$8.40 in 1936. The indicated rise, however, was confined to the period of exceptionally cold weather in the first portion of the year.

Freight rates.—The emergency surcharges in railroad freight rates, averaging about 12 cents a ton, which had been authorized April 18, 1935, continued in effect until June 30, 1936. Effective July 1, they were reduced to an average of approximately 9 cents a ton and remained at that level to December 31, 1936, at which time they were discontinued.

The average freight charge per net ton of revenue bituminous coal was \$2.25 in 1936, as against \$2.24 in 1935. It is evident, therefore, that in 1936, as in earlier years, the average freight charge was considerably greater than the average price of coal, f. o. b. mines (table 7).

Increased mechanization.—A marked increase in the installation of mechanical loading devices is indicated by manufacturers' reports of sales made in 1936 (tables 28 and 29). Sales of mobile loading machines and of conveyors established new records. Returns from 28 manufacturers show sales of 344 mobile loading machines as against 115 in 1935—an increase of 199.1 percent. Sales of conveyors, including those equipped with duckbills, totaled 660 units—an increase of 115 percent. Statistics of the tonnage loaded by machine are not yet available, but it is clear that the final returns will show a large increase over the 47,177,000 tons mechanically loaded in 1935.⁴

Growth of stripping.—Further increase in the stripping of coal occurred in 1936. Six new stripping operations were begun or completed during the year. In Illinois the tonnage produced by stripping increased 21.3 percent, while the tonnage from shaft mines increased only 13 percent. It is clear that the final returns for the country as a whole will show an advance over the record of 1935, when 23,647,292 tons of bituminous coal and lignite were mined by stripping in the United States.

Mechanical cleaning.—Parallel activity marked mechanical cleaning by wet and pneumatic methods in 1936. A total of 36 installations was made during the year, with an annual capacity conservatively estimated at 8,000,000 tons of cleaned coal. Despite the increase in fixed charges, and often in labor, that it entails, mechanical cleaning is strengthening the industry's position in competition with other fuels.

Trend of employment.—The average number of men employed at bituminous-coal mines in 1935 was 462,403. Information so far available points to a slight increase in the number employed during 1936. The monthly employment returns of the Bureau of Labor Statistics,

³ Computed by J. R. Bradley from the Quarterly Trade Returns of the Canadian Government. The value of imports as recorded in the Canadian customs statistics represents the fair market price in the country of origin and excludes transportation costs.

⁴ See chapter on Progress of Mine Mechanization.

FIGURE 45.—Average production of bituminous coal per working day in each month, 1905-36.

covering 1,220 mines in 24 States, show an increase of 3 percent in number employed for 1936 over the previous year. Reports from the mining departments of three States which collect current records of employment indicate an average increase of 2.5 percent over 1935. If these indicators are correct, the total number of men employed at all mines in 1936 should fall somewhere between 467,000 and 476,000 men. In comparison with 1929, when the industry employed 502,993, this represents a decrease of 27,000 to 36,000 jobs.

However, the number of unemployed coal-mine workers probably exceeds 36,000, as even in 1929 considerable numbers of bituminous miners were entirely jobless.

FIGURE 46.—Tonnage of bituminous coal absorbed by the principal branches of consumption, 1917-36.

FIGURE 47.—Monthly movement of bituminous coal in the major channels of distribution, 1935-36.

The increase in number of men employed in 1936 was small in relation to the increase in production. There was, however, an improvement in running time and a substantial gain in total pay rolls. The average hours worked per week at the mines reporting to the Bureau of Labor Statistics rose from 26.3 hours in 1935 to 28.9 in 1936. Pay rolls during the same period increased 21.5 percent.⁵

⁵ U. S. Bureau of Labor Statistics, Employment and Pay Rolls, November 1936, Serial No. R. 495. In February 1936 the average number of hours worked per week at mines reporting was 32.8 hours and in November 1936 31.8 hours.

Trend of capacity.—The latest statistics of mine capacity relate to 1935 (table 2). The long depression, which began in the coal industry immediately after 1923, had forced the closing or abandonment of several thousand mines and the liquidation of active capacity from 970,000,000 tons per year of 308 days in 1923 to 622,000,000 tons in 1934. In 1935, with more men at work and more machinery in use, there was a slight increase in capacity, and the total per year of 308 days amounted to 640,000,000 tons.

The figure of 308 days represents the potential full-time year before the limitation of hours effected by the National Recovery Act Bituminous-Coal Code in October 1933. Under the 5-day week now prevailing, the potential full-time year is approximately 261 days (without allowing for the possibility of staggering work). At 261 days the capacity active in 1935 was 543,000,000 tons against an actual production for the year of 372,373,122 tons.

Trend of fuel efficiency.—Among the largest consumers of coal, indicators point to the conclusion that the savings in fuel efficiency that have been so marked since the war are slowing down. Ten years ago the electric public-utility power plants were saving 6 percent a year in the coal required to generate 1 kilowatt-hour. In 1936, however, the average saving, as compared with the year before, was cut to 1.0 percent, or 0.02 pound per kilowatt-hour. On steam railroads the average consumption per 1,000 gross ton-miles in freight service was reduced from 120 pounds in 1935 to 119 in 1936—a saving of 0.8 percent. Ten or fifteen years ago the annual savings in railroad fuel were averaging 3 percent. (See fig. 53.)

On the other hand, great advances in fuel efficiency probably are continuing in the smaller industrial establishments and in the field of domestic consumption, which together account for a large fraction of the national demand.

Competition of oil and gas.—Competition of oil and gas continued active in 1936. Although the consumption of coal increased in the competitive steamship-bunker, electric-power plant, and railroad-fuel trades consumption of oil in the same trades increased still more. Gas-utility companies sold 6.1 percent more manufactured gas but 17.7 percent more natural gas than in 1935.⁶ There was further expansion in the use of oil burners in the domestic fuel market.

Largely because of the revival of activity in the heavy industries and the pick-up in rail transportation, however, the proportion of bituminous coal in the national energy supply increased. At the low point of the depression, bituminous coal furnished 45.0 percent of the total energy production. In 1935 the proportion was 45.1 percent and in 1936, 47.1 percent. Compared with 1929, however, the proportion furnished by bituminous coal shows a marked decline (tables 8 to 10).

Statistical tables—1936.—Tables 1 to 7 give the statistical record of the bituminous-coal industry in 1936, as indicated by the preliminary data available as this report is written. (See fig. 48.)

⁶ American Gas Association. (Figures cover first 11 months.)

TABLE 1.—*Bituminous coal in 1936 and comparisons with 1929-35*

[All tonnage figures represent net tons]

	1929	1932	1934	1935	1936 (preliminary)	Change 1935-36
Production	534,988,593	309,709,872	359,308,022	372,373,122	434,070,000	+16.6%
Exports to Canada and Mexico ¹	14,727,452	8,428,829	10,212,285	9,043,827	9,911,987	+9.6%

² Production plus imports minus exports plus or minus net changes in consumers' stocks.

³ Association of American Railroads.

⁴ Unweighted average of spot price quotations, f.o.b. mines, on 61 grades and sizes of bituminous coal, as quoted currently in the Coal and Coal Trade Journal. Computed by J. R. Bradley. No attempt was made to weight the various coals nor to test the accuracy of quotations. The figures, however, give a rough measure of the trend of the spot market.

⁵ Data not available.

⁶ Interstate Commerce Commission. Excludes direct freight charges.

⁷ Computed by J. R. Bradley from the Quarterly Trade Returns of the Canadian Government. The value of imports as recorded in the Canadian customs statistics represents the fair market price in the country of origin and excludes transportation costs.

⁸ As reported by J. R. Bradley from records of the U. S. Bureau of Mines.

⁹ Computed by J. R. Bradley from records of the Bureau of Foreign and Domestic Commerce. The average cost declined from \$4.66 per net ton in 1935 to \$4.60 in 1936.

¹⁰ Computed from records of the Bureau of Foreign and Domestic Commerce. The figure represents the average value at the point of export of shipments to all foreign coun-

tries including Canada. Exports to overseas destinations only excluding those to Canada and Mexico, show an increase in average value per ton of 13 cents in 1936 over 1935, but it is uncertain how far this is affected by changes in grades and in freight rates.

¹¹ Bureau of Labor Statistics, with allowance for months between the quarterly returns.

¹² Average receipts per net ton of revenue bituminous coal originated, as reported by the Interstate Commerce Commission.

¹³ Plain, L. N., and Tryon, F. G., Sales of Mechanical Loading and Cleaning Equipment for Use in Coal Mines in 1936; Min. Cong. Jour., February 1937, pp. 57-60.

¹⁴ Figures for 1929 to 1935 are based on the detailed reports of all mine operators producing over 1,000 tons to the U. S. Bureau of Mines. The figure for 1936 is estimated from the monthly employment index of the U. S. Bureau of Labor Statistics, which covers about half of the men employed in the industry, and from current monthly reports of certain State mine departments. The 1936 report of the Colorado mine inspector shows an increase in the number employed of 6.2 percent over 1935, that of the West Virginia Department of Mines shows an increase of 3.0 percent, while that of Illinois indicates no change over the preceding year.

Other local sales, used by employees, etc.....					7,374,143	7,773,619
Total production.....	478,435,267	564,584,082	534,983,593	309,709,872	359,398,022	372,373,122
Number of active mines of commercial size:						
Class 1 (200,000 tons or more).....	694	748	827	485	551	581
Class 2 (100,000 to 200,000 tons).....	837	935	660	477	493	479
Class 3 (50,000 to 100,000 tons).....	959	1,175	668	469	479	553
Class 4 (10,000 to 50,000 tons).....	1,558	2,742	1,361	1,111	1,072	1,068
Class 5 (1,000 to 10,000 tons).....	1,728	3,730	2,541	2,905	3,071	3,716
Total number over 1,000 tons.....	5,776	9,331	6,057	5,427	6,238	6,315
Percent of output from mines in classes 1 and 2.....	75.4	70.4	83.1	77.5	80.5	80.7
Average number of men employed at mines active:						
Underground.....	494,238	600,305	433,999	345,905	384,947	389,942
Surface, including strip pits.....	77,644	104,465	68,994	60,475	73,064	72,461
Total.....	571,882	704,793	502,993	406,380	458,011	462,403
Average number of days mines operated:						
Nominal length of established full-time week.....	232	179	219	146	178	179
Capacity of active mines with existing labor force.....	51.6	48.4	48.5	48.6	40.0 and 35.1	35.1
Per year of 306 days (full time before October 1933):						
Per year of 261 days (5-day week basis).....	635,000,000	970,000,000	752,000,000	653,000,000	822,000,000	640,000,000
Output per man per day.....	538,000,000	823,000,000	638,000,000	584,000,000	827,000,000	543,000,000
Output per man per year.....	3.61	4.47	4.85	5.22	4.40	4.80
Underground output cut by machine.....	837	801	762	762	785	805
Underground output mechanically loaded.....	80.7	68.3	78.4	84.1	84.1	84.2
Quantity mined by stripping.....		0.3	7.4	12.6	12.2	18.5
Quantity cleaned by wet or pneumatic processes.....	1,280,946	11,940,134	20,288,699	19,641,128	20,789,641	23,647,292
	22,099,691	20,140,385	32,371,950	27,357,699	33,858,714	39,511,176

* The earliest year in which figures were collected in strictly comparable form was 1933, when commercial sales by truck and wagon were 15,462,739 tons.

* The increase in number of mines shown for 1934 and 1935 over preceding years is largely due to more complete coverage of small trucking mines made possible by cooperation of the N. E. A. divisional code authorities. See Minerals Yearbook, 1936, pp. 561-564.

* The figures represent the full-time week as reported by the operator, not the hours actually worked by the men.

* Affected by changes in length of working day.

* Figures for 1914, the year of earliest record.

* Exclusive of central washeries operated by consumers.

TABLE 3.—Preliminary statistics of coal production in 1936, by States, with final figures for earlier years

State	Production (thousands of net tons)							Change, percent, 1935-36	Percent of total bituminous

¹ U. S. Geol. Survey and Federal Power Commission. Represents all coal consumed by public utility power plants in power generation, including a small amount of anthracite.

² Bureau of Foreign and Domestic Commerce.

³ Interstate Commerce Commission. Represents bituminous coal consumed as locomotive fuel by class I steam railways, excluding switching and terminal companies. Figure for 1936 partly estimated.

⁴ U. S. Bureau of Mines.

⁵ Obtained by subtracting the known items from the calculated total consumption. Includes general manufacturing, domestic and many miscellaneous uses.

⁶ Production plus imports minus exports, plus or minus changes in consumers' stocks.

⁷ Note that consumption includes the small amount imported.

⁸ Preliminary.

¹ Value of all coal including nonrevenue railroad fuel and deliveries of captive coal to consumer owners, as reported by operators to the U. S. Bureau of Mines.

² Average revenue received by class I steam railroads per net ton of revenue bituminous coal originated, as reported to Interstate Commerce Commission.

³ Interstate Commerce Commission, Bureau of Statistics, Report 23157.

⁴ Preliminary.

SOURCES OF DATA AND ACKNOWLEDGMENTS

Detailed annual statistics.—The data on operation of bituminous-coal mines for 1935 and earlier years given in this report are based upon detailed annual reports courteously furnished by the producers.

The figures include all known operations producing more than 1,000 tons a year.⁷

In the present report the standard unit of measurement is the net or short ton of 2,000 pounds.

These reports, like all others collected by the Bureau of Mines, depend upon voluntary cooperation of the producing companies. The Bureau has no power to compel the submission of reports and has sought none. The system of voluntary reporting has been in use since 1883, when these statistics were inaugurated by the United States Geological Survey, and has served a useful purpose in measuring the simpler facts of production, supply and demand, trends of employment, mechanical equipment, operating practice, and output per man. The voluntary system of reporting is not adapted to the recording of costs, investments, profits, or, it is believed, to the controversial aspects of price differentials, wage rates, and hourly earnings.

The reports of production submitted directly to the Bureau have in most years accounted for fully 97 percent of the total production; and the remaining output, representing chiefly very small mines, has been ascertained with reasonable accuracy from the records of the State departments of mines, which have statutory authority to require reports, or occasionally from railroad carloadings.

In 1935 the Bureau was unable to obtain direct reports from several larger companies whose output ranged from 100,000 to 1,250,000 tons a year. The more important of these operators have mines in Fremont, Las Animas, and Routt Counties, Colo.; Harlan, Hopkins, and Letcher Counties, Ky.; and Greene, Indiana, and West-

⁷ Production figures for 1913 include a certain tonnage from small mines producing less than 1,000 tons a year and those given for 1923 include 1,141,431 tons from "wagon mines shipping by rail."

moreland Counties, Pa. In each instance it was possible to obtain the tonnage, men employed, and days worked by these companies from the public records of the Department of Mines of the State in question; therefore the totals for tonnage, employment, and operating time are believed to be complete and comparable with earlier years.

To the thousands of other companies who continued to cooperate on the voluntary basis, responding courteously to the Bureau's request for information, cordial thanks are extended.

Current production statistics.—The figures of production in 1936 are preliminary estimates based upon (1) railroad carloadings of coal and beehive coke reported weekly or monthly by all the important carriers, (2) shipments by river reported by the United States Engineers, (3) direct reports from a number of mining companies, and (4) monthly production statements compiled by certain local operators' associations and State mine departments. Monthly or weekly reports are received from the Coal Trade Association of Indiana, Hazard Coal Operators Association, Harlan County Coal Operators Association, Kanawha Coal Operators Association, Eastern Ohio Operators Association, New River Coal Operators Association, North Dakota Board of Railroad Commissioners, Utah Coal Operators Association, Virginia Operators Association, West Kentucky Coal Bureau, Winding Gulf Operators Association, and Operators Association of the Williamson Field. Especial acknowledgment for detailed monthly production reports is made to Thomas Allen, Colorado inspector of coal mines; James McSherry, director, Illinois Department of Mines and Minerals; M. J. Hartneady, secretary, Pennsylvania Department of Mines; and N. P. Rhinehart, chief, West Virginia Department of Mines.

In making the estimates, allowance is made for commercial truck shipments, local sales and colliery fuel, and for small trucking or wagon mines producing over 1,000 tons a year. Where a mine is on the border between two States, the production is credited to the State from which the coal is extracted rather than that in which the tipple is located. If the mine extracts coal from lands in both States, the tonnage is apportioned accordingly.

Anthracite and lignite.—The statistics of bituminous coal include, for convenience, the small output of anthracite and semianthracite produced outside Pennsylvania and the production of lignite. Details regarding these coals are given in tables 46 and 47.

The anthracite mines of Pennsylvania, on the other hand, are recognized as a distinct industry and treated separately in part II.

Value at mines defined.—In reporting value of product, the operator is asked to state the "Amount received at the mines, f. o. b. cars, less the selling expense. Value of coal not sold but used by producer, also mine fuel, and coal made into coke should be estimated at average prices that might have been received."

The returns of total value and average value of "sales realization" per ton should be used with these instructions in mind. The figures do not purport to include selling expense; and they are affected, especially in some areas, by the large tonnage of captive coal, the average value reported for which may differ materially from that for sales on the competitive market.

As the inquiry regarding value has been carried in the same form for many years, the replies should furnish a reliable index to the rise and fall in the level of coal prices.

Estimates of value included in statistics.—If an operator who is known to have produced coal during the year will make no report of the value of his product to the Bureau of Mines, an estimate of the value is included in the total to make it complete; as, for instance, in Alabama, where for 7.8 percent of the State's known production no value was reported by the operators.

These estimates are based on a study of the reports of all similarly situated operators in the same county who did report their values.

For several years the proportion of the total value covered by actual reports has exceeded 95 percent. In 1935, because of lack of reports from certain companies of larger size mentioned above, the percentage covered by actual returns to the Bureau of Mines was somewhat smaller. Out of the \$658,063,000 given as the total value of bituminous coal at the mines, \$624,092,000 represents actual reports submitted by the operators to the Bureau or to the State governments, and \$33,971,000 (5.2 percent) represents estimates made in the manner described. The largest proportion represented by estimates in any State was 28.8 percent in Oklahoma; and the smallest was 1.4 percent in Utah.

The average value per ton or sales realization computed for 1935, which amounts to \$1.77, is therefore not a complete count, but essentially a sample based upon 94.8 percent of the known tonnage of the industry.

RELATIVE RATE OF GROWTH OF COAL, OIL, AND WATER POWER, 1889-1936

According to preliminary data the total supply of available energy in the form of coal, oil, and natural gas, and water power in 1936 was 24,134 trillion B. t. u., an increase of 11.7 percent over the year before. This was the largest production of energy in any year since 1929. (See fig. 49.)

The figures are expressed in British thermal units because some common denominator is necessary for such unlike quantities as tons of coal, barrels of oil, and cubic feet of gas. Table 8 summarizes the equivalent in British thermal units of each of the fuels. Water power is represented by the equivalent fuel required to perform the same work.

In converting water power into its fuel equivalent, two alternative assumptions have been made. The first, as in previous issues of these tables, assumes a *constant* fuel equivalent of 4 pounds of coal for each kilowatt-hour of water power produced, throughout the entire period covered by the tables from 1889 to 1936. This factor was selected because it represents in round numbers the average efficiency of all central stations generating steam-electric power in 1913, the midpoint of the period under review. The usefulness of the *constant* factor lies in showing the rate at which water power is being developed. It permits direct comparison between the relative increase in kilowatt-hours of water power and the corresponding increase (or decrease) in tons of coal, barrels of oil, or cubic feet of gas produced. On the other hand, the constant factor makes no allowance for the fact that

coal and other fuels produced today are used more efficiently than formerly.

To throw light on the influence of improving fuel efficiency, a second computation of the energy equivalent of water power has therefore been made. This assumes a *prevailing* fuel equivalent, diminishing year by year, which represents the average performance of all fuel-burning central electric stations for the year in question. This average has declined from about 7.05 pounds of coal per kilowatt-hour in 1899 to 1.44 pounds in 1936. (The *prevailing* factor is thus much above the *constant* factor in 1899 and much below it in 1936.) The *prevailing* fuel equivalent indicates more nearly the amount of fuel that would have been needed in any one year to generate the same power in a steam-electric station. It should be noted, however, that the ultimate uses to which the water power generated is put often displace fuel burned much less efficiently than in central stations and that in any instance no other important branch of fuel consumption has shown advances in fuel efficiency approaching that of the central stations.⁸

As these tables attempt to determine the total energy from all fuels and from water power, the ideal factor for converting water power into fuel equivalent would be the average efficiency of all forms of fuel consumption in each year. No basis for determining such an all-embracing average exists at present but enough is known to be certain that it would show much less reduction from 1899 to 1936 than did the central stations. For the present, a just comparison of the changing contributions of water power and of fuel to the national energy supply would lie somewhere between the results shown by the *constant* equivalent and the *prevailing central-station* equivalent in these tables.

As in earlier issues of these tables, the figures for oil and natural gas represent the entire production of crude petroleum and of gas. Most of this production does not come into direct competition with coal. Much of the supply of both oil and gas is used in regions of the country, such as California and portions of the Southwest, where coal is available only at unusually high cost because of heavy transport charges. Nearly half of the natural gas is used in the field for drilling or operating oil and gas wells and pipe lines, or for the manufacture of carbon black. More than half the oil is used in the form of gasoline, kerosene, and lubricants, for which purposes coal cannot well compete, except at very much higher levels of oil prices. Even these refined products, however, involve a certain measure of indirect competition with coal, for the energy market of the country is becoming more fluid and competitive, and a demand which cannot be met by one source of supply tends to fall back on the others.

The subject of interfuel competition is exceedingly complex, and it would require an elaborate analysis and the accumulation of data not now available to determine even approximately how much of any one fuel has actually been displaced either by other fuels or by water power. The present tables do not permit determination of such displacement; their purpose is rather to measure the long-time trends in the total demand for energy.

⁸ Tryon, F. G. and Rogers, H. O., Statistical Studies of Progress in Fuel Efficiency: Trans., 2d World Power Conference, 1930. From 1917 to 1935 the average saving in unit fuel consumption of electric central stations was 58.5 percent, as against 29.6 percent for railroad freight service and 19.8 percent for iron blast furnaces.

¹ The unit heat values employed are: Anthracite, 13,600 B. t. u. per pound; bituminous coal, 13,160 B. t. u. per pound; petroleum, 6,000,000 B. t. u. per barrel; natural gas, 1,075 B. t. u. per cubic foot. Water power includes installations owned by manufacturing plants and mines, as well as Government and privately owned public utilities. The fuel equivalent of water power is calculated from the kilowatt-hours of power produced wherever available, as is true of all public-utility plants since 1919. Otherwise the fuel equivalent is calculated from the reported horsepower of installed water wheels, assuming a capacity factor of 20 percent for manufactures and mines and of 40 percent for public utilities.

² Assuming 4 pounds per kilowatt-hour, which is the average in round numbers of central electric-station practice in 1913, the midpoint of the period shown.

³ Assuming the average central-station practice for each of the years shown, which declined from about 7.05 pounds per kilowatt-hour in 1899 to 1.44 pounds in 1936.

⁴ Based on the amount of coal displaced by gas as estimated by the gas companies at the time.

⁵ Imports negligible.

⁶ Does not include an unknown amount of bootleg or stolen coal. If this were included, the energy for anthracite would be approximately 1,528 trillion B. t. u. in 1935 and 1,598 trillion B. t. u. in 1936, and the total energy would be increased accordingly.

[†] Preliminary.

Table 9 compares the relative increase in the several sources of energy by means of index numbers in which production for the year 1918 is represented by 100. Production of anthracite in 1936 was 45 percent below 1918 (41 percent if bootleg coal is included). Production of bituminous coal was 25 percent below 1918. Production of domestic petroleum increased 209 percent over 1918, and natural gas increased 188 percent.

There was an increase of 170 percent in the amount of water power developed (represented by the constant fuel equivalent).

TABLE 9.—*Relative rate of growth of coal, oil, and water power in the United States*

[The figures for the year 1918 are represented by the number 100, and the figures for all other years are expressed as a percentage of the 1918 rate]

Year	Pennsylvania anthracite	Bituminous coal	Total coal	Petroleum (total crude)		Natural gas (total production)	Total oil and gas	Water power (at constant fuel equivalent)	Grand total	
				Domestic production	Imports				With water power at constant fuel equivalent	With water power at prevailing central station equivalent

¹ Not available.

² Imports negligible.

³ If illicit or bootleg anthracite were included, the index for 1935 would be 57 and that for 1936, 59.

⁴ Preliminary.

Table 10 gives the percentage composition of the total energy supply, on the alternative assumptions of water power at constant and at prevailing central-station equivalents in fuel. (See fig. 50.) On the assumption of constant equivalent, the proportion contributed by water power has increased from 1.8 percent in 1899 to 9.3 in 1936. On the assumption of prevailing central-station equivalent, it has remained substantially unchanged at between 3 and 4 percent. As already noted, the truth lies somewhere between the two assumptions. On either basis, water power furnishes a relatively small fraction of the total energy budget of the Nation, although, of course, a much larger fraction of the electric power produced by public utilities.

Coal remained the largest source of energy in 1936, contributing 53.3 percent with water power counted at constant fuel equivalent and 56.7 percent with water power at prevailing central-station equivalent.

TABLE 10.—Percent of total B. t. u. equivalent contributed by the several mineral fuels and water power in the United States

Year	Penn- sylvania anthra- cite	Bitu- minous coal	Total coal	Petroleum (total crude)		Natural gas (total production)	Total oil and gas	Total mineral fuels	Water power, fuel equiva- lent	Grand total, includ- ing water power

1936 ² -----	6.6	50.1	56.7	29.0	.9	9.8	39.7	96.4	3.6	100.0

¹ Less than 0.1 percent.² If bootleg coal were included the proportion from anthracite would be 7.0 percent in 1935 and 6.6 in 1936 at constant and 7.5 in 1935 and 7.0 in 1936 at prevailing water power equivalents.³ Preliminary.

FIGURE 50.—Percent of total B. t. u. equivalent contributed by the several sources of energy, counting water power at constant fuel equivalent, 1889–1936.

If water power is counted at the prevailing fuel equivalent of central stations in each year, its proportion is 3.2 percent in 1899 and 3.6 percent in 1936, and the proportions of the other sources of energy are affected accordingly.

FINAL BITUMINOUS STATISTICS FOR 1935

Tables 11 to 47 give the final detailed statistics of bituminous mine operations in 1935. The subjects covered include production, number and size of mines, employment and length of working day, equipment and methods of preparation, fuel economy, stocks, shipments by railroads and waterways, foreign trade, and world production.

The data have been released for immediate use through the Weekly Coal Report as rapidly as the tabulations could be completed. A summary of all the major tables was issued in mimeographed form February 10, 1937 (Bituminous Coal Tables, 1935–36).

Corresponding data regarding expenditures for supplies and materials, colliery fuel, purchased electric power, salaries, and wages were collected by the Bureau of Mines in cooperation with the Census Bureau as a feature of the Census of Business for 1935. These data have been previously released in multigraphed statements by the Census Bureau and are brought together in permanent form in a report published by the Works Progress Administration under the title "Employment and Related Statistics of Mines and Quarries, 1935—Part I, Bituminous Coal."

PRODUCTION

SUMMARY BY STATES

TABLE 11.—Summary of coal produced, value, men employed, days operated, and output per man per day, by States, in 1935

[Exclusive of product of wagon mines producing less than 1,000 tons.¹ For notes as to certain estimates included in totals of value of product, and as to comparability of 1935 figures of employment in Illinois, Indiana, and Pennsylvania, with those for 1934, see detailed tables by States]

State	Net tons				Total quantity	Value		Number of employees			Aver- age num- ber of days mines oper- ated	Man- days of labor ² (in thou- sands)	Aver- age tons per man per day ³	
	Loaded at mines for shipment by rail or water	Commer- cial sales by truck or wagon	Other sales to local trade or used by employees or taken by loco- motives at dumple	Used for power and heat or made into coke at mines ⁴		Total quantity	Total (thou- sand dollars)	Aver- age per ton	Under- ground	Surface

Total 1934.....	328,431,697	18,739,320	7,374,143	4,822,862	359,398,022	628,383	1.75	384,947	65,412	458,011	178	81,724	4.40

¹ The figures relate only to active bituminous-coal mines of commercial size that produced coal in 1935, excluding wagon mines producing less than 1,000 tons.
² Includes coal made into coke at mines in the following States in 1935: Colorado, 78,810 tons; Pennsylvania, 878,144; Tennessee, 6,047; Utah, 11,806; Virginia, 235,498; Washington, 3,978; West Virginia, 254,617; a grand total of 1,467,962 tons in 1935, against 1,647,865 in 1934.
³ Based upon (1) the "reported" number of man-shifts where the operator keeps a record thereof, otherwise upon (2) the "calculated" number of man-shifts obtained by multiplying the average number of men employed underground on the surface at each mine by the number of days worked by the mine and tippie, respectively. Using throughout the "calculated" man-shifts as developed before the year 1932, namely, the product of the total number of men employed at each mine times the tippie days, the average output per man per day was 4.56 in 1935, a figure strictly comparable with 3.66 in 1930, previously published.

TOTAL PRODUCTION SINCE BEGINNING OF MINING

TABLE 12.—Coal produced, by States, 1925-35, with production of maximum year and cumulative production from the earliest record to the end of 1935, in thousands of net tons

State	Maximum production		Production by years											Total production from earliest record to end of 1935

¹ Northeastern Kentucky field includes McRoberts district.² Hazard field includes Whitesburg district.³ Cahaba Group includes North Carolina (no. 92) to avoid disclosure.⁴ Leavenworth field, Kansas, includes Grundy field, Missouri (no. 71) and Platte field, Missouri (no. 72).⁵ California includes Arizona, Idaho, and Oregon.⁶ As in 1934, the 1935 figures of total number of mines are not comparable with years before 1934 in a number of States because of more complete coverage of small trucking mines made possible by cooperation of the Divisional Code Authorities. See Minerals Yearbook, 1936, pp. 561-564.

PRODUCTION, BY WEEKS AND MONTHS

The following tables summarize the statistics of weekly and monthly production of bituminous coal first published in the Bureau of Mines Weekly Coal Reports. The figures are estimates based upon daily and weekly statements of cars of coal and beehive coke loaded by the principal railroads and of shipments over the Monongahela, Allegheny, Ohio, and Kanawha Rivers. The estimates are revised afterward to

agree with the results of the annual statistical reports from the coal producers; therefore the figures given here differ slightly from the estimates originally issued in the weekly reports.

For the method used in counting holidays see Coal in 1930, page 631.

TABLE 14.—*Estimated weekly production of bituminous coal in 1935*

¹ Figures represent output and number of working days in that part of the week included in the calendar year shown. Total production for the week of Jan. 5, 1935, was 7,435,000 net tons; for the week of Jan. 4, 1936, 8,385,000 net tons.

² Average daily production for the entire week and not for the working days in the calendar year shown.

TABLE 15.—*Monthly production of coal, by States, in 1935, in thousands of net tons*

[The totals for the year are based on final complete returns to the Bureau of Mines from all operators known to have produced more than 1,000 tons a year. The apportionment of the known yearly total among the 12 months is based on the best information available, in some States upon direct tonnage reports from operators to the State mine department; in most cases upon current records of railroad car loadings and waterway shipments.]

¹ As in 1934, the 1935 figures of total number of mines and of number in class 5 (less than 10,000 tons) are not comparable with years before 1934 in a number of States because of more complete coverage of small trucking mines made possible by cooperation of the Divisional Code Authorities. See Minerals Yearbook, 1936, pp. 561-564.
² Includes Alaska, Arizona, California, Georgia, Idaho, North Carolina, and Oregon.

LABOR STATISTICS**MEN EMPLOYED**

The method of collecting employment statistics is explained in detail in *Coal in 1929*, pages 738 to 740. These statistics are believed to represent the most accurate returns obtainable under present conditions, both as to the records generally available in mine offices and as to the funds allotted to the Bureau of Mines for collecting data. (See fig. 51.)

For a detailed explanation of the classification of mine employees see *Coal in 1930*, page 651. Tables 11 and 44 show the number of men employed underground and on the surface, by States and counties, during 1935.

Bureau of Mines statistics of men employed purport to represent the average number on the rolls of mines active during the year on the days when the mine was in operation.⁹

In computing the average number, the Bureau excludes pay periods when the mine was shut down and giving employment only to maintenance men. Chiefly for this reason, the Bureau of Mines' record of numbers employed shows a higher result than does the average number of wage earners computed at the decennial Censuses of Mines and Quarries of 1909, 1919, and 1929, since the Census average includes the shut-down periods. The differences between the two methods of computation are discussed at length in "Employment and Related Statistics of Mines and Quarries, 1935, part I, Bituminous Coal."¹⁰

The Bureau's method is believed to give a more accurate measure of the working force of the coal industry. It is also necessary, however, to take account of the time lost by the men on the rolls through intermittent operation. This is best done by recording separately the factor of mine operating time, as indicated by the average number of days worked. In 1935, the bituminous-coal mines operated an average of 179 days. So important is the element of intermittent employment in coal mining that it requires separate measurement, but to measure it in the factor of days worked as well as in the average number of men employed would be to count double.

The two factors of average number of men employed when the mines are in operation and average number of days operated, taken together give the best available measure of employment opportunity in this industry. For 1935, this means that an average of 462,403 men was employed at bituminous-coal mines and that the mines operated 179 days.

DAYS OPERATED

All statistics of days of mine operation issued by the Bureau of Mines represent weighted averages in which the operating time of each mine is weighted by the number of its employees. A number of States that collect statistics of mining, publish figures of days worked that are

⁹ A special case arises when mines operate under local share-the-work or staggering agreements and divide the available work among two or more groups of men who work alternately. A few mines, chiefly in Illinois and Indiana, have followed this practice in recent years. Prior to 1935, some of these mines reported to the Bureau the average number of men working and others the total number on the rolls. Beginning with 1935, special arrangements have been made to count only the number working. For the effects of this practice on the employment record in Illinois and Indiana, see footnotes to table 44.

¹⁰ Published as Report E-3, Works Progress Administration National Research Project on Reemployment Opportunities and Recent Changes in Industrial Techniques.

simple averages of all mines reporting, without regard to size. Such an unweighted average is likely to be unduly depressed by the small mines, which generally operate less steadily than the larger, and hence tend to understate the amount of work available to the typical worker. In the interest of uniformity and accuracy it is urged that all such statistics should be weighted, and the method used by the Bureau is recommended as the simplest and most accurate.

MAN-DAYS OF LABOR

Tables 11 and 44 give the best record available of the man-days of labor performed in 1935. A small proportion of bituminous-mine operators keep an accurate record of the man-days or man-hours worked, which is utilized by the Bureau wherever reported. The great majority of the mines, however, indicate that they keep no such record. In that case, the man-days are calculated by the Bureau by multiplying the number employed underground and on the surface by the number of days operated by the mine and tippie, respectively. Although the computations of man-days are made mine by mine, the resulting product is necessarily an approximation and is subject to a considerable margin of error.

Until the American coal industry arranges to keep an accurate record of man-days or man-hours worked, all computations of accident rates, daily earnings, and output per man will remain subject to material qualifications. In the meantime, the computed product of men times days remains the only comprehensive measurement available.

LENGTH OF WORKING DAY

The following tables summarize the replies of mine operators to the question, "Number of hours operated per shift."

The reports of more than 7 hours in 1935 consist partly of (1) cases where the operator has included time when the men are entering or leaving the mine, (2) cases where the operator has reported the time of certain occupations that work longer than other employees, as in stripping overburden, or (3) cases where work is staggered and two crews of men overlap. There were, however, a number of mines in 1935 where the established day was 8 hours. Most of these, as shown by the table, were very small. Numerous mines, especially the smaller ones, failed to answer the question.

Among the mines replying to the inquiry, it was found that 97.8 percent of the men employed were in 7-hour mines and that the weighted average working shift was 7 hours.

The established working day does not of itself measure the length of time that men actually work or the time that they are underground, because of the possibility of overtime, because the mine may sometimes shut down before the full day is over, because the miner may go home before the mine stops, and because he spends a considerable time in going to and from his place of work underground. As interpreted in the wage agreements, the 7-hour day means 7 hours of labor at the usual working place, exclusive of any time for lunch and exclusive of the time spent in going from the entrance of the mine to the working place and back again. (See Coal in 1930, p. 656.)

¹ Includes a few small mines where the day was more than 9 or less than 7 hours or was irregular, or where it was changed during the year.

The trend in the length of the working day over the last 32 years is summarized in table 18. As noted, these figures represent the operator's statement of the nominal operating day for the mine. They do not purport to represent the time actually worked by the men. On the one hand, they make no allowance for cases where tonnage or piece workers leave early. On the other hand, they make no allowance for cases where tonnage men continue at work after the mine as a whole is shut down, or go into the mine to work on days when the tippie is idle. Such work beyond the established hours became more frequent in the unorganized areas during the years prior to the N. R. A. code and may have had a material effect in increasing the average hours actually worked, especially in the period 1930 to 1932. This would also affect the calculated output per man per day.

TABLE 18.—*Percentage of men employed in bituminous-coal mines that had established working days of 7, 8, 9, and 10 hours, 1903-35*¹

Year	Percent of total employees in—				Weighted average working day (hours)
	7-hour mines	8-hour mines	9-hour mines	10-hour mines

After Oct. 2.....		99.8	.1	.1	8.00
Average for year.....		94.4	3.7	1.9	8.07
1934:					
Before Apr. 1 ²		99.8	.1		8.00
After Apr. 1 ³	97.3	2.6	.1	(⁴)	7.03
Average for year ⁴	73.0	26.9	.1	(⁴)	7.27
1935.....	97.8	2.0	.2	(⁴)	7.02

¹ Calculated on basis of total number of men in mines definitely reported as having 7-, 8-, 9-, or 10-hour day. A small number of mines that work more than 10 hours or less than 7 hours (8 prior to Apr. 1, 1934) have been excluded, as have also all mines for which the reports were defective. Data not available for 1909.

² Data as reported for 1933 "after Oct. 2."

³ Data as reported for December 1934.

⁴ Less than 0.05 of 1 percent.

⁵ In computing the average for the year the percentages for "before Apr. 1" have been weighted by 3 months and percents "after Apr. 1" by 9 months.

FIGURE 51.—Trends of employment, working time, mechanization, and output per man at bituminous coal mines, 1899-1936.

EQUIPMENT AND METHODS OF MINING AND PREPARATION
METHODS OF RECOVERY
TABLE 19.—Bituminous coal mined by different methods, by States, in 1935

¹ Probably includes some "permissible" machines not so specified by the operators.

STRIPPING OPERATIONS

TABLE 21.—*Stripping operations of all types in the bituminous-coal fields, by States and counties, in 1935*

[Returns for mines that recover coal both by stripping and by underground operations do not permit separating men engaged in stripping from those engaged in other work. For this reason the figures of men employed represent all persons working at these mines, including those underground. The total tons produced by both methods at these same mines are also shown]

State and county	Num-ber of strip pits	Number of power shovels		Coal produced (net tons)		Total value at same mines	Average value per ton	Number of employees				Average number of days mines operated	Per-cent of county or State total mined by strip-ping	Man-days of labor	Average tons per man per day	
		Steam	Elec-tric	All others	Mined by strip-ping			Total at same mines	Under-ground	Surface						Total

Horse stripping operations.....	90	—	—	—	98,507	1.82	415	83	2.86
Mines combining stripping and underground methods in same operation ⁶	16	14	1	3	281,721	2.04	1,067	175	4.41
Grand total.....	368	174	139	194	23,647,292	1.49	11,043	195	11.21

¹ Exclusive of coal produced by underground mining in the same operation.² Items in these columns include underground mining conducted in the same operation.³ Includes Arkansas, Colorado, Michigan, South Dakota, Texas, and Wyoming.⁴ Includes operations in Alabama, Arkansas, Kentucky, Montana, North Dakota, Ohio, Pennsylvania, and Wyoming, in which the output was obtained by both methods. In addition to the 281,721 tons produced by stripping, this group of 16 mines obtained 541,153 tons by underground methods, its total production by both methods being 822,874 tons.

LOADING MACHINES AND CONVEYORS, WITH SALES IN 1936

Mechanical loading in 1935.—The figures of mechanical loading refer to all mechanical devices designed to reduce the labor of hand shoveling into mine cars. The data for 1935 are based upon complete returns courteously furnished by coal operators to the Bureau of Mines.¹¹

¹¹ The Bureau appreciates the cooperation of the manufacturers of loading equipment and of the Pennsylvania Department of Mines, the Illinois Department of Mines and Minerals, the State coal-mine inspector of Wyoming, and Jonas Waffle of Indiana in furnishing information used in the compilation.

TABLE 23.—*Tonnage of bituminous coal loaded mechanically underground in 1935*

	Net tons	Percent
Loaded by machine:		
Mobile loading machines.....	24, 675, 248	86. 9
Scraper loaders.....	1, 118, 201	3. 9
Conveyors equipped with duckbills and other self-loading devices.....	2, 594, 564	9. 2
Total loaded by machine.....	28, 388, 013	100. 0
Handled by conveyors:		
Conveyors equipped with duckbills and other self-loading devices.....	2, 594, 564	12. 1
Pit-car loaders.....	11, 098, 466	51. 9
Other hand-loaded conveyors.....	7, 690, 745	36. 0
Total handled by conveyors.....	21, 383, 775	100. 0
Recapitulation, less duplications:		
Mobile loading machines.....	24, 675, 248	52. 3
Scraper loaders.....	1, 118, 201	2. 4
Pit-car loaders.....	11, 098, 466	23. 5
Other conveyors, including conveyors equipped with duckbills and other self-loading devices.....	10, 285, 309	21. 8
Grand total loaded mechanically.....	47, 177, 224	100. 0

TABLE 24.—*Comparative change in tonnage loaded by principal types of machines, 1934-35*

	1934 net tons	1935 net tons	Increase (+) or decrease (—), 1935	
			Net tons	Percent
Mobile loading machines.....	20, 749, 534	24, 675, 248	+3, 925, 714	+18. 9

¹ Includes mobile loading machines, scrapers, and conveyors equipped with duckbills and other self-loading heads.² Includes hand-loaded conveyors and pit-car loaders.³ Number of mines in which hand-loaded conveyors (other than pit-car loaders) were used.⁴ Included under "Undistributed" to avoid disclosing individual operations.

Sales of mechanical loading equipment in 1936.—The trend of mechanization in 1936 is indicated by the manufacturers' sales of equipment made during the year. Tables 28 and 29 show the number of loading devices in use in 1935 and the number of new machines shipped into various geographical areas in 1936. Further details are given in the chapter on Progress in Mine Mechanization.

TABLE 28.—*Number of mobile loaders and scrapers sold in 1936 compared with the number in actual use in 1935, by regions*

	Mobile loaders		Scrapers	
	In use in 1935	Sales in 1936	In use in 1935	Sales in 1936
Northern Appalachian States:				
Pennsylvania—central.....		6	19	2

Indiana.....	123	22		
Trans-Mississippi States: Colorado, Montana, New Mexico, Oklahoma, Utah, and Wyoming.....	100	15	32	6
Total bituminous.....	657	344	78	19

¹ Includes sales in east and west Kentucky.

TABLE 29.—*Number of conveyors sold in 1936 compared with the number in actual use in 1935, by regions*¹

	Conveyors in use in 1935 ²	Sales of conveyors in 1936 ³
Northern Appalachian States:		
Pennsylvania—central, and Maryland.....	347	44
Pennsylvania—western.....		33
Ohio.....		49
Southern Appalachian States:		
West Virginia—northern.....	8	32
West Virginia—southern.....	63	207
Virginia.....	44	32
Kentucky.....	15	36
Alabama and Tennessee.....	78	55
Middle Western States: Illinois and Indiana.....	12	18
Trans-Mississippi States: Arkansas, Colorado, Iowa, Missouri, Montana, Oklahoma, Utah, Washington, and Wyoming.....	282	154
Total bituminous.....	849	660

¹ The figures of number in use in 1935 are not exactly comparable with the number sold in 1936 because of uncertainties in defining what constitutes a conveyor. The comparison, however, will serve to indicate which regions have made the largest proportionate increases.

² Includes hand-loaded conveyors and conveyors equipped with duckbills or other self-loading heads.

³ East Kentucky only in 1935.

⁴ Includes a small number sold for use in western Kentucky.

MECHANICAL CLEANING

Data on mechanical cleaning of coal are given in tables 30 to 35, inclusive. The figures are based on reports furnished by coal operators. (See fig. 52.) The manufacturers of cleaning equipment have also cooperated. For a review of the growth of mechanical cleaning the reader is referred to Statistical Analysis of the Progress in Mechanical Cleaning of Bituminous Coal from 1927 to 1934, by L. N. Plein, Economic Paper 18, Bureau of Mines, 25 pages.

TABLE 30.—*Bituminous coal mechanically cleaned by wet and pneumatic methods, 1934-35, in net tons of clean coal*

	1934	1935	Increase (+) or decrease (-), 1935	
			Net tons	Percent
By wet methods:				
At the mines.....	27,555,730	31,006,643	+3,450,913	+12.5
At central washeries operated by consumers.....	3,972,845	5,849,845	+1,877,000	+47.2
Total wet.....	31,528,575	36,856,488	+5,327,913	+16.9
By pneumatic methods.....	8,297,984	8,504,533	+206,549	+2.5
Grand total.....	39,826,559	45,361,021	+5,534,462	+13.9

TABLE 31.—*Classification by types of equipment used in cleaning bituminous coal, 1934-35*

[Coal cleaned at central washeries operated by consumers in Colorado and Pennsylvania is included]

	Net tons of clean coal		Increase (+) or decrease (-), 1935		Percent cleaned by each type	
	1934	1935	Net tons	Percent	1934	1935
Wet methods:						
Jigs.....	14,012,058	15,735,039	+1,722,981	+12.3	35.2	34.7
Concentrating tables ¹	1,116,154	1,117,789	+1,635	+1	2.8	2.5
Jigs in combination with concentrating tables ¹	1,227,413	1,549,422	+322,009	+26.2	3.1	3.4
Launders and upward-cur- rent classifiers.....	15,167,450	18,454,238	+3,286,788	+21.7	38.1	40.7
Unspecified.....	5,500	-----	-5,500	-----	0	-----
Total wet.....	31,528,575	36,856,488	+5,327,913	+16.9	79.2	81.3
Pneumatic methods.....	8,297,984	8,504,533	+206,549	+2.5	20.8	18.7
Grand total.....	39,826,559	45,361,021	+5,534,462	+13.9	100.0	100.0

¹ Information obtained in 1935 indicated that 1 of the plants classed as using jigs only in 1934 was actually using jigs in combination with concentrating tables. The figures for 1934 have been revised accordingly.² A more representative figure for the use of wet tables is indicated by combining the totals for concentrating tables with the total for jigs in combination with concentrating tables. This shows a net gain of 323,644 tons (13.8 percent) for 1935.TABLE 32.—*Total production of all coal at mines with cleaning plants, 1934-35, in net tons*

[Does not include any estimate for mines that may ship to consumer-operated plants]

	1934	1935	Increase (+) or decrease (-), 1935

FUEL ECONOMY

TABLE 36.—*Indicators of the effect of fuel economy on consumption of coal per unit of performance since the World War*

	Pounds	Reduction (percent)
Steam railroads:		
Pounds per 1,000 gross ton-miles freight service:		
Average, 1919-20.....	170	-----
Average, 1935.....	120	29.4
Pounds per passenger-train car-mile:		
Average, 1919-20.....	18.5	-----
Average, 1935.....	15.5	16.2
Electric-public-utility power plants:		
Pounds per kilowatt-hour, 1919.....	3.2	-----
Pounds per kilowatt-hour, 1935.....	1.5	53.1
Iron and steel—pounds coking coal per ton of pig: ¹		
1919.....	3,577	-----
1935.....	2,838	20.7
Coke manufacture: Savings of heat values through recovery of gas, tar, light oils, and breeze by extension of byproduct in place of beehive coking, 1913-35, expressed as percent of coal used for all coke in 1935: ²		20.0

¹ Includes only savings through higher yields of merchantable coke per ton of coal charged and lower consumption of coke per ton of iron. Excludes economies through recovery of byproducts, which are treated in next item.

² These byproducts are used in part for boiler fuel, in part for metallurgical purposes, in part for domestic heating and cooking, and to a small extent for automotive fuel.

FIGURE 53.—Trends in fuel efficiency in the United States, 1917-36.

STOCKS OF COAL HELD BY CONSUMERS

BITUMINOUS COAL LOADED FOR SHIPMENT BY INDIVIDUAL RAILROADS AND WATERWAYS

The table shows the quantity so originated on each railroad and waterway, as reported by mine operators in answer to the following inquiry:

Railroads or waterways on which product was first loaded for shipment:

Name of road or waterway

(Give shipments over each road separately)

Tons

As these statistics include nonrevenue railroad fuel they may differ from statistics compiled by the railroad companies, which often show only revenue freight and include coal received from connecting lines

or coal shipped off the Lake docks, as well as that originating at mines on the lines reporting.

Where the road serving the district is a subsidiary of a larger road some operators may report their coal as loaded on the subsidiary and others as loaded on the parent system (a few subsidiaries have been consolidated under the name of the parent road).

In general, the figures are given under the name reported by the operator; and the Bureau of Mines does not attempt to combine them under the name of the larger system, believing that such combination can best be made by those using the figures, as they are probably familiar with coal-traffic problems. If such combination is made, the total will usually be found to check reasonably well with the statistics issued by railroads that keep records of total coal originated.

TABLE 38.—*Bituminous coal loaded for shipment in 1935 by individual railroads and waterways, as reported by operators, in net tons*

FIGURE 54.—Twenty-seven years' exports of bituminous coal to Canada and Mexico, the Caribbean, and "overseas" destinations.

SHIPMENTS TO ALASKA, HAWAII, AND PUERTO RICO

In addition to the export trade proper, the United States supplies a small tonnage of anthracite and bituminous coal to the Territories of Alaska, Hawaii, and Puerto Rico. In 1935, 26,554 tons were shipped to Alaska, 1,695 tons to Hawaii, and 21,760 tons to Puerto Rico.

DETAILED STATISTICS OF BITUMINOUS COAL, BY STATES AND COUNTIES

TABLES OF PRODUCTION, VALUE, MEN EMPLOYED, DAYS OPERATED, MAN-DAYS OF LABOR, AND OUTPUT PER MAN IN 1935

Table 44 presents detailed statistics for each coal-producing county from which three or more operators reported production. If less than three reports were received, the figures for two or more counties have been combined to avoid disclosing individual returns, unless permission to publish has been granted by the producers.

The series gives the details of total value of product, average value per ton, men employed above and below ground, average number of days worked by the mines, and output per man per day. The figures include stripping operations as well as deep mines. Separate particulars for the stripping operations in each county are given in table 21. If the reader will deduct the stripping figures as given in that table from the totals for all mines in the following table he will find that the remainder represents the operations of the deep mines. By this means figures can be obtained for the deep mines separately in any State or county desired.

In response to many requests for data on the amount of coal shipped from mine to consumer by motortruck, the Bureau of Mines in 1932 for the first time asked the mine operators to supply such information. For the last 3 years this tonnage has been shown as "Commercial sales by truck or wagon." (See column 2 of table 44 for 1935.)

Because of a change in the method of reporting, the statistics of average production per man per day for 1932 to 1935 are not precisely comparable with those for earlier years. Before 1932 they were based on the calculated number of man-shifts, obtained by multiplying the average number of men employed at each mine by the number of days worked at the mine. Since 1932, operators have been asked to make a special report of the number of man-shifts actually worked

wherever the necessary record was kept. The number of operators able to furnish this information was small, except in certain Far Western States. The reported man-shifts were utilized wherever possible to improve the accuracy of the record. Otherwise, the man-shifts were calculated by multiplying the number employed underground and on the surface by the number of days worked by the mine and tippie, respectively.

To facilitate comparisons with former years, the Bureau has also computed the output per man per day for 1935, using the calculated method throughout. The result for Alabama was 2.84 tons; Alaska, 5.13; Arizona, California, Idaho, and Oregon, 1.72; Arkansas, 2.53; Colorado, 4.43; Georgia and North Carolina, 1.30; Illinois, 6.27; Indiana, 8.46; Iowa, 2.84; Kansas, 4.32; Kentucky, 4.26; Maryland, 3.17; Michigan, 2.70; Missouri, 4.20; Montana, 9.62; New Mexico, 3.31; North Dakota, 8.15; Ohio, 4.46; Oklahoma, 3.24; Pennsylvania, bituminous, 4.11; South Dakota, 2.46; Tennessee, 3.06; Texas, 5.47; Utah, 7.10; Virginia, 3.93; Washington, 3.70; West Virginia, 4.78; and Wyoming, 6.37.

In this form, the 1935 figures are precisely comparable with those for the years prior to 1932.

TABLE 44.—*Production, value, men employed, days operated, man-days of labor, and output per man per day at bituminous-coal mines in specified States and counties in 1935*

[Note that figures relate only to active mines of commercial size, excluding wagon mines producing less than 1,000 tons. Waste and refuse are not included in tonnage. The statistics of average tons per man per day in 1935 are based upon (1) the reported number of man-shifts, where the operator keeps a record thereof; otherwise, upon (2) the calculated number of man-shifts, obtained by multiplying the average number of men employed underground and on the surface at each mine by the number of days worked by the mine and tipples, respectively. They are not precisely comparable with the figures published for the years prior to 1932, which were based on a calculated method throughout, but in most States the discrepancy is slight.]

¹ No coal was made into coke at mines in 1934 or 1935.

² The figures of number of men employed in 1935 are not strictly comparable with those for 1934. In Illinois during recent years from 28 to 45 mines have divided the available working time among their employees. In 1934 some of these mines reported to the Bureau the average number of men working when the mines were active, and others the total number on the rolls, so that the aggregate number reported for that year was approximately 1,600 in excess of the average number actually working. For 1935 the figures represent the average number working. If all men on the pay rolls of the mines dividing work are included, the total number of men employed in 1935 is found to be 46,129.

³ Much of the output of the State is obtained from strip pits or by the use of loading machines, in which types of operations the production per man is large.

⁴ The indicated increase in output per man-day in 1935 is partly due to the activity of strip mines, and partly to more accurate measurement of the number of man-days at certain underground mines where the available working time was divided among the men on the rolls. If allowance is made for these factors, the actual increase in output per man-day at deep mines was slight.

⁵ The figures of number of men employed in 1935 may not be strictly comparable with those for 1934, because of differences in reporting at certain mines which divided working time among their employees by local agreement. The 1935 figures here given represent in all cases the average number of men working, rather than the total number on the rolls, so far as disclosed by the information at hand. If all men on the pay rolls of the mines dividing work were included, the aggregate number employed in 1935 would be somewhat greater than the 11,347 here shown.

¹ No coal was made into coke at mines in 1934 or 1935.

¹¹ Production of 1 mine, the tipple of which is in Leavenworth County, Kans., is credited to Platte County, Mo., where the workings are located.

¹² The output is chiefly obtained from strip pits in which the production per man per day is large.

TABLE 44.—*Production, value, men employed, days operated, man-days of labor, and output per man per day at bituminous-coal mines in specified States and countries in 1935*—Continued

¹ No coal was made into coke at mines in 1934 or 1935.

² Revised figures.

³ The output is chiefly obtained from strip pits, in which the production per man per day is large.

⁴ Most of the indicated increase in output per man-day in 1935 was due to strip mining, but there was a slight gain at underground mines also.

⁵ Includes coal made into beehive coke at mines in the following counties in 1935: Allegheny, 1,800 tons; Bedford, 5,397; Blair, 1,196; Cambria, 61,908; Fayette, 456,938; Indiana, 41,985; Westmoreland, 308,920. The State total was 878,144 tons in 1935, against 1,136,937 tons in 1934.

⁶ The figures of number of men employed in 1935 may not be strictly comparable with those for 1934. The report form in both years asked for "average number of men employed, excluding coke workers and office force", but certain supplementary questions asked in 1935 may have led operators to make more consistent allowance for seasonal fluctuations in employment and for elimination of coke workers and office force. (This would also affect the comparability of the output per man per day.) If at any mine available working time was divided by agreement among the men on rolls, the 1935 returns purport to represent the average number working rather than the total number on the rolls. The 1935 figures have been carefully checked, but it should be noted that the report of the State Department of Mines shows an increase in number employed of 1,478 men over the year 1934.

TABLE 44.—*Production, value, men employed, days operated, man-days of labor, and output per man per day at bituminous-coal mines in specified States and counties in 1935*—Continued

¹ No coal was made into coke at mines in 1934 or 1935.

² Includes 424 tons made into coke at mines in Morgan County and 5,623 tons in "Other counties (southeastern)" in 1935, a total of 6,047 tons (compared with a total of 12,502 tons in 1934).

³ Includes 11,808 tons made into coke at mines in Carbon County in 1935 (25,153 tons in 1934).

⁴ Includes 235,498 tons made into coke at mines in Wise County in 1935 (131,275 tons in 1934).

¹ No coal was made into coke at mines in 1934 or 1935.

² Much of the output of the State is obtained from strip pits or by the use of loading machines, in which types of operations the production per man is large. Includes 3,478 tons made into coke at mines in Pierce County in 1935 (2,686 tons in 1934).

³ Includes 266,617 tons made into coke at mines in Fayette and Preston Counties in 1935 (281,195 tons in 1934).

DETAILED STATISTICS OF LIGNITE AND OF ANTHRACITE AND SEMIANTHRACITE OUTSIDE OF PENNSYLVANIA

The summary tables of this report dealing with bituminous coal include for statistical convenience the operations of lignite mines and of mines producing anthracite and semianthractite outside of Pennsylvania.

While these coals constitute a small proportion of the national total, locally they are distinct and important industries. To meet the needs of those concerned, separate figures are given in tables 46 and 47.

For a detailed analysis of the hard-coal industry outside of Pennsylvania see Coal in 1930, pages 721 to 726.

TABLE 46.—Production, value, men employed, days mines operated, and output per man per day at lignite mines in 1935

[Includes all coal produced in the areas mapped as "lignite" in U. S. Geol. Survey Prof. Paper 100-A. Note that subbituminous coal, sometimes known as "black lignite", is not included]

PART 2.—PENNSYLVANIA ANTHRACITE ¹²

By F. G. TRYON, H. L. BENNETT, AND J. R. BRADLEY

There were a number of important developments in the anthracite industry during 1936. Demand improved, a wage agreement was concluded, and Anthracite Industries, Inc., was organized. The plan to coordinate prices, initiated in 1935, was continued.

Production.—Production of anthracite increased about 5 percent over 1935. According to preliminary figures, the total output of the legitimate operations was 54,760,000 tons, including a relatively small quantity of semianthracite from Sullivan County (see table 1A).

Shipments of all sizes from breakers and washeries in 1936 totaled 46,979,000 tons, an increase of 5.2 percent over 1935. The greater part of the increase of 2,336,000 tons occurred in the last quarter of the year.¹³ (See fig. 55.)

¹² Data for 1936 are preliminary; detailed statistics with final revisions will be released later. Data for 1935 are final.

¹³ Anthracite Bureau of Information.

The principal statistics for 1935 and 1936 are summarized below:

TABLE 1A.—*Salient statistics of the Pennsylvania anthracite industry, 1935-36*

[Including colliery fuel, dredge and washery coal. All tonnage figures represent net tons of 2,000 pounds]

	1935	1936 ¹	Percent of change in 1936
Production	52, 158, 783	54, 760, 000	+5.0
Value at mines:

Exports	1, 609, 000	1, 678, 000	+4.3
Imports	571, 000	615, 000	+7.7
Consumption (calculated)	51, 100, 000	54, 199, 000	+6.1
Number of men employed ³	103, 269	102, 300	— .9

¹ Figures for 1936 are in most instances preliminary and subject to revision.

² Bureau of Labor Statistics, with allowance for months between the quarterly returns.

³ Figures for anthracite in 1936 are estimated from the report of the Pennsylvania Department of Mines, with allowance for employees of dredge operators and strip contractors.

The foregoing figures do not include the output of unauthorized mines, exact statistics of which are not obtainable. An estimate of the Anthracite Institute for 1936 is approximately 2,500,000 tons. This tonnage is in addition to the official statistics of production. Thus, the illicit production of and trade in anthracite continued to be a problem. Late in the year the Governor of Pennsylvania announced that a commission would be appointed to investigate and report on the situation.

FIGURE 55.—Trends of production and stocks of Pennsylvania anthracite, 1928-36.

Consumption.—Consumption, based on production, plus imports, minus exports, and the change in producers' stocks at the beginning and end of the year was 54,199,000 tons, an increase of 6.1 percent over the 1935 (revised) figure. Sales of unauthorized coal have not been considered in either year.

Distribution.—Loadings at Lake Erie ports amounted to 689,000 tons, an increase of 23.3 percent over 1935. Receipts at Duluth-Superior increased 69.8 percent in comparison with 1935. Shipments off lake docks also increased, in this case 17.2 percent. Tidewater receipts of anthracite in the New England States (including imports)—1,398,000 tons—were approximately the same as in 1935, and receipts by rail were slightly below the 1935 tonnage. Total receipts in New England declined 2.2 percent.

Trend of stocks.—Producers' stocks in the first quarter of 1936 averaged about 300,000 tons a month less than in the corresponding quar-

ter of 1935, were about 150,000 tons a month more during the following 6 months, and in the last quarter were approximately 500,000 tons a month less than in the December quarter of 1935. At the close of the year stocks were 500,000 tons less than in 1935.

Stocks on lake docks in January (220,000 tons) reached the low point in April and the peak in August (444,000 tons) and closed the year at 323,000 tons—10 percent greater than in 1935.

Stocks held by 233 representative dealers totaled to 472,000 tons in January, reached the low point in March at 381,000 tons and the high in July at 679,000 tons, and in December were 593,000 tons, or slightly above the 1935 figure.

Stocks at electric power utilities changed very little during the 12 months and averaged 1,100,000 for the year, a figure almost identical with that for 1935.

The weather.—The mean temperature in the chief anthracite-consuming area in January was about 3° above normal, February 3° below normal, and March 6° to 8° above normal. From September, to November, inclusive, the mean temperature was about 2° below normal and December 4° to 6° above normal.

The heavy rains and resulting flood in the spring of 1936 forced the closing of certain properties and later entailed heavy expense for pumping. It is probable that while the flood brought downstream unusually large quantities of fine material, dredge operators will find increased difficulty in separating the debris from the coal.

Industry cooperation.—A "coordinator" was appointed for the New York City market, where a fair-trade-practice agreement and open price posting was adopted. The coordinator also endeavors to eliminate the competition of illicit anthracite. Producers and wholesalers, as well as retailers, cooperated in the scheme.

Anthracite Industries, Inc.—In the summer of 1936, Anthracite Industries, Inc., was organized as a cooperative effort by anthracite producers to promote the greater use of anthracite.

Representatives of the organization have been located in 17 of the anthracite-burning areas; their duties include coordinating the efforts of the retailers, the equipment manufacturers, the equipment dealers, and the heating contractors. Demonstrations were held in a number of cities where automatic heating devices using anthracite were displayed.

Prices.—During the first quarter of 1936 the circular price of anthracite stove coal was the same as in the corresponding quarter of 1935, but in the succeeding 5 months was above the 1935 figure, while in the last quarter the price was \$0.50 below the 1935 figure. The circular price of buckwheat remained the same as in 1935. (See fig. 56.)

A preliminary estimate, based on returns from companies representing two-thirds of the tonnage, indicates that the average value of all shipments, local sales, and colliery fuel in 1936 was \$4.13 per ton compared with \$4.03 in 1935. If confirmed by final reports from the companies not yet heard from, this points to a slight increase in average sales realization compared with the year before. The realization, however, was still far below the \$5.22 obtained in 1929.

Signs of a slight increase in average realization during 1936 are also found in the prices paid by Canadian buyers for American anthracite. The Canadian Government, for customs purposes, keeps a

record of the fair market value of the coal imported, computed at the point of origin f. o. b. mines. For 1935 and 1936 this record shows the following average prices paid per net ton:

	1935	1936	Change
Prepared sizes, including pea.....	\$6. 21	\$6. 36	+\$0. 15
Sizes below pea.....	2. 85	3. 20	+. 35
All sizes.....	5. 82	5. 96	+. 14

The value at the mines of the anthracite produced in 1936 is estimated at \$226,000,000, an increase of 7.6 percent over 1935.

FIGURE 56.—Monthly prices of Pennsylvania anthracite, f. o. b. mine, as quoted by the trade journals, 1913-36. Prices are averages of the range as quoted on the New York market.

¹ Subject to revision.

² As reported by the Anthracite Institute.

³ Less than 500 tons.

⁴ Quoted by trade journals in New York market.

⁵ Computed from Quarterly Trade Returns of Canada.

⁶ Bureau of Labor Statistics, curb delivery.

⁷ No data.

⁸ Bureau of Labor Statistics index numbers.

Exports.—Anthracite exports in 1936 were 4.31 percent greater than in 1935. Of the 1936 exports 71.6 percent was cleared through the Buffalo customs district. Canada took 99.0 percent in 1935 and 99.2 percent in 1936. Imports of anthracite into the United States in 1936 were 36.7 percent of exports.¹⁴

Changing sources of supply characterized the market for anthracite in Canada.

Imports of anthracite into Canada in 1934, 1935, and 1936 were 3,537,000, 3,451,000, and 3,561,000 tons, respectively. In 1934, 1935, and 1936 the United States supplied 51.0 percent, 48.4, and 47.3 percent, respectively; Great Britain, 46.5 percent, 42.1, and 36.8 percent, respectively; Germany, 2.0, 5.9, and 10.6 percent; French Indochina, nil, 1.6, and 3.5 percent; Belgium, 0.5, 2.0, and 1.3 percent; and the Netherlands, nil, nil, and 0.4 percent, respectively.

The estimated displacement of coal by natural gas used for domestic purposes in Canada in 1935 was 640,000 tons, the highest figure since 1931, when the amount was 680,000 tons. Fuel oil for domestic use and building heating also gained, the amount representing 784,000 tons of coal in 1934 as against 693,571 tons in 1933.¹⁵

Imports.—Imports of foreign anthracite into the United States increased 7.7 percent over 1935. Nearly three-fourths of the total originated in Russia and practically all of the remainder in Great Britain. As usual, nearly all of the imports entered the New England States.

Imports of coke into New England States and New York increased from 198,041 tons in 1935 to 203,127 in 1936. Coke imports from Belgium ranked first and were two and one-half times greater than the previous year; the Canadian figures did not differ greatly, but a decrease took place in receipts from Germany and Great Britain. About 36 percent of the imports entered the New York customs districts and 22 percent the Massachusetts, 19 percent the Los Angeles and San Francisco, and 9 percent the Buffalo district.

Imports of fuel briquets amounted to 20,350 tons, an increase of 21 percent over the 1935 figure. All were imported from Belgium and entered the Massachusetts customs district.

Freight rates.—The motor-compelled rates applicable to anthracite handled by rail, which became effective in 1935, were maintained during the year.

Competitive fuels.—A further increase in the use of competitive fuels for domestic consumption is indicated for 1936. The statistical trend of the competition of other fuels with anthracite may be found in the chapter on Coke and Byproducts. (See p. 920.)

Range- and heating-oil sales continued to show increases. Sales of range oil amounted to 21,526,000 barrels in 1935 compared with 15,756,000 in 1934; the New England States, New York, and New Jersey took 16,952,000 barrels, an increase of 3,380,000 over 1934. Sales of heating oils proper, for domestic and commercial purposes, totaled 76,853,000 barrels in 1935, an increase of 26.3 percent over 1934. The 1934 figure was an increase of 21.3 percent over 1933. In 1935, for the first time, oils used for heating exceeded those used for the bunkering of vessels.

¹⁴ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

¹⁵ Coal Statistics for Canada, 1934 and 1935, p. 8.

Sales of natural gas to domestic consumers, which includes gas used for house heating, increased 8.3 percent over 1935, according to the American Gas Association. Sales in 1936 in New York were 4.3 percent and in Pennsylvania 9.2 percent more than in 1935.

Sales of manufactured gas for domestic cooking, water heating, and gas lighting decreased slightly in comparison with 1935. Sales for house heating, however, again showed a noteworthy increase—21 percent over 1935.

Sales of liquefied petroleum gases increased sharply, jumping from 509,000 barrels in 1935 to 714,619 in 1936, or 40.4 percent. Sales in 1935 were 21 percent over the 1934 figure.

The use of byproduct coke for domestic purposes amounted to 9,643,507 tons in 1936 compared with 9,161,980 in 1935, and sales of beehive coke sold for domestic purposes totaled 377,836 tons as against 264,406 in 1935.

The production of fuel briquets totaled 1,124,973 tons—30.7 percent more than in 1935. In 1936 briquets manufactured in the Eastern States comprised 31.2 percent of the national production compared with 35.9 percent in 1935. The average value per ton in the Eastern States continued to decline, having been \$4.72 in 1934, \$4.48 in 1935, and \$4.19 in 1936. Packaged-fuel data are not included in the foregoing. Imports of briquets in 1935 and 1936 were 16,778 and 20,350 tons, respectively. The production of petroleum coke declined from 1,458,000 tons in 1935 to 1,378,000 in 1936, or by 5.5 percent.

Sales of both mechanical stokers and oil burners again increased. Sales of mechanical stokers for residences and apartment houses in 1936 totaled 80,924, an increase of 82.7 percent over 1935. Sales in 1935 were 73.7 percent over 1934. Shipments of domestic oil burners in 1936 numbered 157,413 (41.9 percent over 1935), which was about 43 percent over the 1934 figure.

Wage agreement.—A new wage agreement between anthracite mine operators and the United Mine Workers of America was consummated early in the year and approved by the Tri-District Convention in June 1936. The agreement, which expires April 30, 1938, mainly provides for a 7-hour day and a 5-day week from May 1, 1937, at the same daily wage rate as was previously paid for 8 hours, and the complete check-off of union dues by the operators. A clause also provides for full responsibility on the part of district and international officers of the United Mine Workers of America to prevent strikes in violation of the agreement.

Employment.—The number of men employed at the anthracite mines declined from 103,269 in 1935 to 102,300 in 1936, or about 1 percent, according to the Pennsylvania Department of Mines, with allowance for employees of dredge operators and strip contractors. Employment in 1935 was 5.4 percent less than in 1934. The number of men on strike in 1935 was the lowest since 1930.

Mechanical loading.—All the related facts of deep-mined production, tons mechanically loaded, and purchases of new equipment indicate the continuing importance of mechanized loading in the anthracite field.

Tables 17A to 20A, inclusive, show the coal mechanically loaded through 1935. In 1935, 9,279,057 tons were handled compared with 9,284,486 tons in 1934, a slight decline of 5,429 tons. In connection

with this small drop note that the total production of deep-mined anthracite was 43,679,000 tons in 1935 and 48,574,000 tons in 1934. A further advance in the degree of mechanized loading is therefore recorded for 1935 in that 21.2 percent of the deep-mined output was mechanically handled compared with 19.1 percent in 1934.

Preliminary reports to the Pennsylvania Department of Mines indicate a total of 11,019,235 tons of anthracite loaded mechanically in 1936, and it is known that large purchases of new equipment were made during the year.¹⁶ In 1935, mine operators reported 1,593 conveyors in use, including hand-loaded types as well as those equipped with duckbills or other self-loading heads. In 1936, 28 manufacturers of equipment reported that 312 new units were sold, which compares with 354 units sold by the same manufacturers in 1935. It is not possible to segregate these sales as to whether they were for replacement of worn-out or obsolete machinery, or for entirely new installations to replace hand loading.

FINAL STATISTICS OF ANTHRACITE IN 1935

SOURCES AND ACKNOWLEDGMENTS

Tables 3A to 27A present the final detailed statistics of operations in the anthracite industry in 1935. The principal data were issued in the mimeographed report *Pennsylvania Anthracite Coal Tables, 1935*, released January 16, 1937, and the detailed record is preserved for permanent reference in this volume.

The statistics are based upon reports courteously furnished by mine operators under the system of voluntary cooperation used in all statistical services of the Bureau of Mines.

The Bureau's standard inquiries relate to production, value of product, employment, and mechanical equipment of the mines. In 1935, certain supplementary questions were asked regarding cost of materials, fuel and power, wages paid, and number and total compensation of salaried employees. These additional items were requested for 1 year only and were added to avoid what would otherwise have been serious duplication of statistical questionnaires. A general Census of Business had been undertaken for the year 1935, designed to cover all branches of American industry and trade. At the suggestion of the Central Statistical Board, it was arranged that these supplementary inquiries regarding anthracite should be carried on the Bureau of Mines annual return. The Bureau was responsible for their collection and tabulation, and throughout the records remained in the confidential custody of its sworn employees. The results have been published in multigraphed form by the Bureau of the Census, and a detailed report has been issued under the title, "Employment and Related Statistics of Mines and Quarries, 1935, Part II—Pennsylvania Anthracite."¹⁷

To all operators responding to the unusually heavy requests for information in 1935, cordial thanks are extended.

The tables in the present chapter are confined to the standard items covered in previous reports of the Bureau of Mines.

FIELDS AND OPERATIONS INCLUDED

The Pennsylvania anthracite industry.—Trade practice and historical usage recognize two major divisions in the coal industry of the United States—bituminous coal and Pennsylvania anthracite. Anthracite and semianthracite are mined in parts of Virginia, Arkansas, Colorado, and New Mexico. Locally these coals represent distinct and important industries; but the tonnages involved are small, and for statistical convenience they are usually grouped with the totals of the bituminous coal industry, and they have been so grouped in this report. Separate figures, however, are given in table 47.

The Pennsylvania anthracite industry, as here defined, includes all the nonbituminous fields of that State. Trade usage commonly includes with Pennsylvania anthracite the output of the Bernice Basin in Sullivan County, although the coal of this basin is officially classified as semianthracite, according to the tentative standard of coal classification adopted by the American Society for Testing Materials.

Districts and fields.—The main anthracite region is divided into three subregions or districts—Lehigh, Schuylkill, and Wyoming. This is the areal grouping most commonly used in trade statistics, and it is followed also in the district organization of the United Mine Workers of America, in which district 1 corresponds to the Wyoming trade region, district 7 to the Lehigh region, and district 9 to the Schuylkill region. The district grouping, therefore, is used in the primary tables of this report. For technical operating studies, however, a grouping into four fields—Northern, Western Middle, Eastern Middle, and Southern—is preferred because it follows more closely the geologic conditions which largely influence the methods and costs of mining. The field grouping is followed in tables 7A and 9A. The Northern field is coterminous with the Wyoming district. That part of the Southern field lying east of Tamaqua, known as the Panther Creek Valley, and the Eastern Middle field make up the Lehigh district. That part of the Southern field west of Tamaqua and the Western Middle field comprise the Schuylkill district.

Small mines and intercompany sales.—No attempt was made to cover the production of illicit or bootleg coal, the quantity of which produced in 1935 has been variously estimated at approximately 4,000,000 tons. All known legitimate operations are included in the statistics. In recent years, conditions have favored the development of numerous small mines operating on lease or subcontract and producing run-of-mine coal, which is sold to larger companies for preparation at a breaker. At the same time there has developed an increasing transfer of coal from one operation to another, and one of the largest companies has built great central breakers to which coal from numerous collieries is shipped by rail for preparation. These tendencies have increased the complexity of the task of compilation, but great care has been exercised to avoid double counting of the tonnage produced by one operator and prepared for market by another, so that the figures are believed to represent the net quantity of merchantable coal plus the fuel used by the collieries themselves. At the same time, the employees of operators producing run-of-mine only have been included, since they have received wages from the industry and have contributed to the final product.

Reports from stripping contractors.—On account of the great increase in the quantity of coal mined by stripping, the Bureau of Mines has for some years made special arrangements to record the employees of strip contractors. A special report is obtained from all known strip contractors of the number of men employed and days worked during the year. In 1935 it was found that an average of 3,053 men was employed by the strip contractors. These men are properly to be counted in the working force of the industry and are included in the tables of this report. Care is taken, however, to avoid double counting of production between the contractor and the colliery company for which the work is done.

STATISTICAL SUMMARY

TABLE 3A.—*Statistical trends of the Pennsylvania anthracite industry, 1931-35*

PRODUCTION, BY WEEKS AND MONTHS

The following tables summarize the statistics of weekly and monthly production of anthracite first published in the Bureau of Mines' weekly coal reports. Statistics of current output are estimated from records of cars of anthracite loaded by the nine railroads that serve the region, checked in turn against tonnage reports from trade sources. The weekly and monthly figures, as given in tables 4A and 5A, have been adjusted to the annual total ascertained by direct canvass of the operators themselves.

TABLE 4A.—*Estimated weekly production of Pennsylvania anthracite in 1935, in net tons*

Week ended	Weekly production	Number of working days	Daily average	Week ended	Weekly production	Number of working days	Daily average

¹ Figures represent the output of working days in that part of the week included in the calendar year 1935. Figures of total production for the week of Jan. 5, 1935 are 1,108,000 tons, and for Jan. 4, 1936, 1,202,000 tons.

² Average daily production for the entire week and not for the working days that fell in the calendar year 1935.

¹ Production is estimated from weekly car loadings as reported by the Association of American Railroads and includes mine fuel, coal sold locally, and dredge coal. Does not include an unknown amount of "boot-leg" production. In computing the average rates per working day, New Year's, Eight-Hour Day (Apr. 1), Memorial Day, Independence Day, Labor Day, Mitchell Day (Oct. 29), Thanksgiving Day, Christmas, and, since the war, Armistice Day, have been counted as holidays. Beginning with 1927, Washington's Birthday is counted as a half holiday. No allowance, however, has been made for church holy days, which are observed by many of the miners. Monthly statistics from 1905 to 1925 will be found in Coal in 1925, pp. 427-428, and from 1926 to 1930 in Coal in 1930, p. 741.

FRESH-MINED AND CULM-BANK COAL, BREAKER AND WASHERY PRODUCT

Anthracite is now produced from three sources—from mines, from old culm banks, and from the rivers that drain the anthracite region. As all three sources contribute to the country's supply, it is important to consider them all to ascertain the total production. No difficulty is experienced in separating the figures of production by dredges. It is difficult to draw a sharp line that can be maintained throughout the statistics of the industry, however, between the fresh-mined and the culm-bank coal.

As the best solution of this problem, the producing companies are asked to supply separate statements for each breaker, washery, or dredge. These are totaled to form the primary tables of this report to show the total quantity of breaker product, washery product, and dredge product, with related figures of value, number of employees, and time worked.

The figures of breaker and washery product, however, are not exactly equivalent to the fresh-mined and culm-bank coal because of the practice sometimes adopted of putting culm-bank coal through a breaker, either directly from the bank or after preliminary treatment in a washery.

In 1935, the total washery product was reported as 2,106,969 net tons. In addition, a total of 617,350 tons of culm-bank coal was treated at breakers. Of this, 192,790 tons was handled in the Lehigh district, 188,584 tons in the Schuylkill district, and 235,976 tons in the Wyoming district.

A record, by fields, of the culm-bank coal put through breakers is given in table 9A.

TABLE 9A.—*Culm-bank coal put through breakers, by fields, 1929-35, in net tons*

Year	Northern	Eastern Middle	Western Middle	Southern	Total ¹

TRENDS IN VALUES AND PRICES

SOURCES OF INFORMATION AND METHODS OF ANALYSIS

Margins of sales agents not included.—The valuation figures in this study represent value at the breaker or washery reported by the operating companies. In making its report, the company is requested to "estimate value of the product not sold" and to "exclude selling expenses."

From this it will be seen that when a producing company sells its output to a separately organized sales company (the practice of many, including certain of the larger producers), the value reported will exclude the margin of the sales company and may therefore be somewhat less than the circular price at which the coal in question is placed on the general market. This fact should be borne in mind in considering the variations in value between different regions shown in the tables for the same sizes of coal. (See table 12A.)

Estimates included in figures of value.—The reports are furnished in writing and signed by responsible officers of the mining companies. If a mine known to have produced coal during the year will make no report of value, an estimate is included in the total to make it complete. In 1935 the proportion of the total value of product represented by such estimates was 2.6 percent, as all operators except a few small producers supplied the information in detail.

AVERAGE SALES REALIZATIONS

The average sales realizations on each size from 1933 to 1935 are given in table 12A. To insure comparability the table is based on shipments of breaker coal only, the dredge and washery product being excluded.

The average realization on breaker shipments in 1935, all sizes combined, was \$4.29 per net ton, a decrease of 24 cents per ton compared with the 1934 average of \$4.53. The 1935 average sales realization was the lowest obtained by anthracite operators since 1918.

In the domestic sizes there was a marked decrease in the price obtained for all sizes. The average mine price of all steam sizes increased from \$1.98 in 1934 to \$2.03 in 1935, chiefly because of the higher price realized on Buckwheat No. 2.

TABLE 12A.—Average sales realization per net ton on Pennsylvania anthracite shipments from breakers, by regions and sizes, 1933-35

Grand total.....	4.46	4.19	1.32	4.27	4.18	4.19	1.27	4.03

¹ Value given for shipments is value at which coal left possession of producing company f. o. b. mines and does not include margins of separately incorporated sales companies.

NUMBER OF OPERATIONS

Due to the many changes in anthracite practices during the past few years, particularly with regard to concentration of preparation at central breakers, it has not been possible to make the figures on number of active plants comparable with earlier years. However, in 1935 an effort was made to make an accurate count of the number of active operations. The results are shown in table 14A.

TABLE 14A.—Number of active operations in the Pennsylvania anthracite industry, 1935

District and type of product	Total active plants reporting ¹	Breakers ²	Other preparation plant ³	Washeries ⁴	Culm banks operated in conjunction with breakers	Dredges	Reporting strip-pit tonnage

Dredges.....	31	-----	20	-----	-----	31	-----
Total.....	344	136	45	8	27	31	89
Sullivan County: Breakers.....	6	6	-----	-----	-----	-----	2
Grand total.....	350	142	45	8	27	31	91

¹ The number of active plants contains numerous duplications, that is, successions known and unknown, and leases and subleases. Each report received which was tabulated for production or for employment has been counted separately.

² Equipped to prepare standard sizes of fresh-mined coal.

³ For preliminary crushing, screening, or cleaning. Usually old breakers are used for this purpose. The number reported for dredges represents reports showing men employed at tipple.

⁴ Preparation plant for the sizing and cleaning of culm-bank coal.

LABOR STATISTICS

Summary of byproducts.....	899	Shipments by rail.....	924
Value and yield of byproducts.....	899	Exports and imports.....	924
Technical developments.....	900	World production.....	926
Coke and other domestic fuels.....	900	Coke-oven byproducts.....	927
Coke for domestic heating.....	900	Summary of byproducts.....	927
Supplies of fuels for domestic purposes.....	901	Coke-oven gas.....	929
Coke and coke breeze.....	901	Tar.....	931
Monthly and weekly production.....	901	Ammonia.....	932
Production by furnace and nonfurnace plants.....	904	Light oil and its derivatives.....	932
Production by States and districts.....	905	Naphthalene.....	933
Number and type of ovens.....	906	Byproduct coke ovens owned by city gas companies, included by Bureau of the Census in manufactured-gas industry.....	933
Capacity of byproduct ovens.....	907		

The coke industry made marked progress in 1936. The total value of all the products of the coke industry in 1936 was \$368,652,221, a gain of \$78,243,789 (27 percent) over 1935. Production of coke was 46,275,184 net tons, an increase of 32 percent compared with 1935. Byproduct ovens operated at 72 percent capacity compared with 55 percent in 1935 and 34 percent in 1932.

The average price of byproduct coke was \$5.06 per net ton in 1936, the same as in 1935. The average value of beehive coke also remained the same in 1936 as in 1935, namely, \$3.91 per net ton. The average price of coal charged in byproduct ovens decreased from \$3.82 in 1935 to \$3.69 in 1936. The amount of coal needed to make 1 ton of byproduct coke was 1.42 tons and the cost was \$5.24 compared with 1.43 tons costing \$5.46 in 1935. The amount of coal needed to make 1 ton of beehive coke was 1.58 tons and the cost was \$2.94 compared with 1.60 tons costing \$2.85 in 1935. (See fig. 60.)

The increase of 32 percent in coke production is due largely to the increase of 46 percent in pig-iron production. Production of byproduct coke at furnace plants was 32,076,089 net tons, an increase of 39 percent over 1935. This directly reflects the increase in pig-iron production in 1936.

Although the total production of coke in 1936 was only 77 percent of that in the year of peak production (1929) it is significant that the trend has been definitely upward since the low of 1932, when production was only 36 percent of the 1929 output. (See fig. 57.)

In 1936, 1,471 beehive ovens were abandoned, and byproduct coke represented 96.3 percent of the total production compared with 97.4 percent in 1935.

FIGURE 57.—Average daily production of beehive and byproduct coke and pig iron, also producers' stocks of byproduct coke, 1930-37, by months.

The total value of products resulting from carbonization of coal in byproduct ovens (coke, byproducts, and breeze) was \$361,935,207 compared with a total cost for coal charged into coke ovens of \$233,224,305. This represents an enhancement of \$128,710,902 in value or 55 percent more than the cost of the raw material.

Sales of domestic coke, which have grown steadily and consistently up to and including 1933, remained about the same in 1934, declined in 1935, and increased slightly in 1936. Sales increased from 9,426,386 net tons in 1935 to 10,021,343 in 1936. Average value of domestic coke at byproduct ovens was \$5.84 per ton in 1935 and \$6.07 per ton in 1936.

Scope of report.—The continuing need for economy in public expenditure impels the Bureau of Mines to confine this report to presenting, through selected tables, the essential facts of the statistical record for the year. If not readily found any derivative figures carried in earlier reports will be furnished by the Bureau upon application.

This report covers only coke made by high-temperature carbonization of coal in beehive and byproduct ovens. However, byproduct coke produced by city gas companies is included. (See fig. 58.) The essential product of these companies is manufactured gas, but in 1936 the production of byproduct coke by city gas companies constituted about 8 percent of the national production of byproduct coke. With respect to ownership and accounting these byproduct ovens are part of the gas utility system, and the Bureau of the Census therefore groups them within the manufactured-gas industry under

the title "The Gas and Coke Industries." In other respects, however, these ovens form part of the byproduct-coke industry and they are so included in the statistics of the Bureau of Mines. The differences in classification are followed advisedly by the Bureau of the Census and Bureau of Mines after consultation with leaders of the gas and coke industries, and the two offices have collaborated in the collection and analysis of the statistics. (See table 50.)

Coke is made by other processes not included in this chapter. In 1936 about 1,083,000 net tons of gas-house coke were made by high-temperature carbonization of coal in types of equipment other than coke ovens—chiefly horizontal retorts. About 1,378,200 net tons of petroleum coke, a byproduct of petroleum refining, were produced in 1936. The manufacture of coke from coal-tar pitch is

FIGURE 58.—Production of petroleum coke, gas-house coke, and beehive and byproduct coke in the United States, 1900-1936. No figures on production of petroleum coke are available before 1914, when the production was 213,777 tons.

established on a commercial basis but the tonnage produced is small. Within the last few years, also, production of a smokeless fuel by low-temperature carbonization of coal has been established commercially in the United States.¹ None of these other kinds of coke, however, are discussed in this report. Only coke from byproduct and beehive ovens is adapted to blast-furnace and foundry uses, which consume most of all coke produced. Practically, therefore, the coke trade is concerned only with beehive and byproduct-oven coke (fig. 58).

The standard unit of measurement in the coke industry is the short or net ton of 2,000 pounds, and unless otherwise specified this unit is employed throughout this report.

¹ See discussion of low-temperature carbonization in the chapter Recent Developments in Coal Preparation and Utilization, by A. C. Fieldner.

TABLE 2.—Statistical trends of the coke industry, 1923 and 1933-36

	1923	1933	1934	1935	1936

Production of coke.—The total production of coke was 46,275,184 tons in 1936 compared with 35,141,261 tons in 1935, an increase of 32 percent. The production of byproduct coke was 44,569,121 tons, an increase of 30 percent over 1935; and the production of beehive coke was 1,706,063 tons, an increase of 86 percent over 1935. The leading States, in order of importance in the manufacture of byproduct coke, were Pennsylvania, Ohio, Indiana, New York, and Alabama. The production of each of these States exceeded 3,000,000 tons in 1936, and their combined output equaled 72 percent of the national production. Pennsylvania and West Virginia lead in the production of beehive coke, their combined output having been 85 percent of the total national output.

Byproduct coke produced at plants classified as furnace plants totaled 32,076,089 tons, an increase of 39 percent over 1935, while production at merchant byproduct plants increased only 12 percent. The increase in coke production at furnace plants is a result of the larger output of pig iron, which was 46 percent higher in 1936 than in 1935. Nonfurnace or merchant plants enjoy the greater stability of a diversified coke market, and the changes in production each year are not of the same magnitude as those at furnace plants when there are widely fluctuating demands for pig iron. Nearly 29 percent of the merchant byproduct coke is manufactured at plants owned by city gas companies. The production of coke at gas-company plants is fairly constant each year, and this has a stabilizing effect on the amount of merchant coke produced each year. On the other hand, furnace-coke production tends to vary with pig-iron production. Normally, the production of coke at furnace plants is nearly 80 percent of all byproduct coke made. In 1936, 72 percent of the byproduct coke was manufactured at furnace plants compared with 54 percent in 1932 and 67 percent in 1935. Table 9 shows the fluctuations in monthly production of coke at furnace plants compared with the fairly uniform monthly production at other plants.

Monthly production of coke increased fairly steadily from 3,446,800 tons in January to 4,599,700 tons in December. The monthly output of byproduct coke showed a similar trend. The production of beehive coke declined during the summer months. (See table 4.)

Value and price of coke.—The value of byproduct coke at the ovens was \$225,695,719 in 1936, an increase of 30 percent over 1935 values. The value of beehive coke at the ovens was \$6,678,272, an increase of 86 percent over 1935. The average value of both byproduct and beehive coke in 1936 remained the same as in 1935, or \$5.06 and \$3.91 per ton, respectively. The lower cost of coal charged in ovens (\$3.82 in 1935 and \$3.61 in 1936) is partly reflected in the lack of change in the price for coke. Values and prices for the various grades of beehive and byproduct coke are shown in tables 27, 28, and 33. Average monthly prices (quoted by Steel) remained fairly uniform throughout the year in the 11 markets given in table 35.

Number and capacity of ovens.—At the end of 1936 there were 12,849 byproduct ovens and 13,012 beehive ovens in existence. During the year 210 new byproduct ovens and 1,343 new beehive ovens were completed. In 1936, 40 byproduct ovens and 1,471 beehive ovens were abandoned. The number of beehive ovens has decreased from 60,432 at the end of 1924 to 13,012 at the end of 1936.

Production of byproduct coke in 1936 was 72 percent of the calculated capacity of all byproduct ovens compared with 34 percent in 1932 and 55 in 1935. (See table 16.) If the byproduct coke ovens had been operated at 90 percent capacity, at the end of 1936 their potential output would have been 56,000,000 tons of coke, nearly equaling the 59,883,845 tons of byproduct and beehive coke manufactured in the peak year 1929.

Coal charged in coke ovens.—In 1936, 65,941,675 tons of coal were charged into coke ovens; of this quantity, 63,243,517 tons were used in byproduct ovens and 2,698,158 tons in beehive ovens.

The leading States mining coking coal, in order of importance, are Pennsylvania, West Virginia, and Kentucky. Of the 63,777,942 tons of coal purchased for use at byproduct plants, 57,334,950 tons (90 percent) were mined in these three States.

Coal cleaned mechanically before being charged into byproduct ovens represented 24.3 percent of that charged in 1936 compared with 23.8 percent in 1935.

Consumption of coke.—The indicated consumption of coke in 1936 was 47,032,147 tons compared with 35,613,824 in 1935, iron furnaces using 31,255,648 tons (66 percent). (See table 25.) For data on consumption by uses see tables 27 and 28.

Stocks of coke.—On January 1, 1937 stocks of coke were 1,732,066 tons, 1,097,318 tons less than on January 1, 1936. Stocks of furnace and foundry coke on January 1, 1937, were 421,305 tons lower than on January 1, 1936, and stocks of domestic and other grades were 676,013 tons lower.

Exports and imports.—Exports of coke in 1936 were 670,312 net tons valued at \$4,191,135 compared with 613,975 tons valued at \$3,590,143 in 1935. Imports were 329,957 tons, an increase of 12,578 tons over 1935, and the value increased from \$1,574,578 to \$1,635,501.

Gross value and yield of byproducts.—The gross value of all the byproducts recovered in 1936, not including breeze, was \$120,205,633. If breeze also is counted as a byproduct, the total value becomes \$127,471,248.

The average yield of byproducts per ton of coal charged has increased notably since the Bureau began to keep records of operating performance. (See fig. 62.) During the depression, the calculated average yields were affected by the closing down of certain ovens or plants, but the long-time trend is unmistakably upward. Since 1915 the average yield of tar has increased from 7.1 to 8.86 gallons, and the average quantity of surplus gas available for sale or use has increased from 4,325 to 6,860 cubic feet.

Four of the 85 byproduct plants active in 1936 produced no ammonia during the year. The 81 plants continuing to recover ammonia obtained an average yield of 22.14 pounds of sulphate per ton of coal carbonized. (See table 47.)

Of the 85 plants active in 1936, only 62 recovered light oil. The average yield obtained by these 62 plants was 2.91 gallons per ton. (See table 48.) The production of motor benzol increased from 58,379,910 gallons in 1935 to 85,672,953 in 1936. Naphthalene sold by byproduct coke operators increased from 13,214,108 pounds in 1935 to 34,946,890 in 1936.

Unit values of byproducts.—Gas is the most important byproduct in value, followed by light oil and derivatives, tar, and ammonia in the

order named. (See table 42.) The unit value of the surplus gas sold or used by all plants declined from 18.2 cents per M cubic feet in 1935 to 16.3 cents in 1936. The average for all plants, however, is much affected by the relative activity of the furnace and merchant plants. The latter group, especially the plants affiliated with gas-utility systems, obtain much higher prices for their gas than do the furnace group. A better indication of the trend is given by the average values reported for the two groups, which are as follows:

Year	Furnace plants	Merchant plants	Total	Year	Furnace plants	Merchant plants	Total
	<i>Cents</i>	<i>Cents</i>	<i>Cents</i>		<i>Cents</i>	<i>Cents</i>	<i>Cents</i>
1929.....	11.6	30.2	16.6	1935.....	11.3	28.9	18.2
1933.....	12.0	29.6	20.3	1936.....	10.8	27.6	16.3
1934.....	11.8	28.6	19.1				

The shift in relative activity of furnace and merchant plants also affects the computed gross values of the several byproducts per ton of coke, shown in figure 61.

The unit values of crude light oil and light-oil derivatives generally were higher in 1936 than in 1935. (See table 42.) The unit values of tar increased slightly, while those of ammonia showed little change. However, because of increased production, the total values of all of the principal byproducts were higher in 1936 than in 1935, despite the change in unit prices.

Technical developments.—The reader is referred to the chapter on Recent Developments in Coal Preparation and Utilization for a review of coke technology during 1936. During the past year the Bureau of Mines has issued reports on the carbonization properties of the Clintwood bed in Virginia, the Pittsburgh bed in Pennsylvania, and the Miller's Creek bed in Kentucky.

COKE AND OTHER DOMESTIC FUELS

Coke for domestic heating.—For domestic heating coke offers certain advantages in cleanliness compared with bituminous coal, and in many localities it is cheaper than the prepared sizes of anthracite.

The marketing of domestic coke is not a simple merchandising problem because coke has burning characteristics different from those of either anthracite or bituminous coal. Therefore to introduce coke in any market area successfully and to hold customers after sales are made it is necessary to carry on expensive educational campaigns. Figure 59 shows how the total sales of domestic coke have risen since 1921, even in the depression years that followed the boom of the late twenties. Total sales of domestic coke (byproduct and beehive) amounted to 7,511,023 tons in 1929 and the volume of sales increased an average of 750,000 tons each year until 1933, when 10,491,037 tons were sold; in 1934 sales were 10,520,295 tons, an increase of only 29,258 tons over 1933; in 1935 sales dropped to 9,426,386 tons, a decline of 1,093,909 tons (10 percent); and in 1936 sales rose to 10,021,343 tons, an increase of 594,957 tons (6 percent).

A more detailed examination of the trend shows that sales of domestic coke at merchant plants increased from 5,986,373 tons in 1930 to 7,595,108 in 1933, then declined to 7,238,296 tons in 1934,

dropped still further to 7,012,739 tons in 1935, and rose to 7,646,714 tons in 1936. Sales of domestic coke at furnace plants increased each year from 1,900,059 tons in 1930 to 2,935,818 in 1934, but fell to 2,149,241 tons in 1935 and dropped still further to 1,996,793 tons in 1936. The decline in sales of domestic coke at furnace plants in recent years is due largely to the fact that these plants are consuming more of their own product and selling more to other industrial consumers, with the result that less coke reaches the domestic market. The trend in sales of domestic beehive coke has been erratic, being as low as 118,665 tons in 1931 and as high as 346,181 tons in 1934. In 1936 beehive sales amounted to 377,836 tons, an increase of 43 percent over 1935.

FIGURE 59.—Growth of sales of domestic coke, byproduct coke, and gas-house coke, 1918-36.

Supplies of fuel for domestic purposes.—More domestic coke was sold in 1936 than in 1935. Statistics for all of the other fuels are not available for 1936, but the trend since 1932 indicates increasing domestic consumption of anthracite, oil, and natural gas. (See table 29.)

The introduction of natural gas into the Middle West through long-distance pipe lines has afforded a new competitive fuel in some parts of that area. The amount of natural gas consumed for domestic and commercial heating in the Middle West has been increasing.

COKE AND COKE BREEZE

MONTHLY AND WEEKLY PRODUCTION

TABLE 4.—Byproduct, beehive, and total coke produced in the United States, 1933-36, by months, and average per day, in net tons

TABLE 21.—*Coal used in manufacture of byproduct coke in 1936, by fields of origin, in net tons*

[Based upon detailed reports from each coke plant. The difference between these totals and those shown in tables 3, 19, etc., is due to change in stock, loss of weight in handling, and the fact that these sometimes represent purchases during the year rather than actual consumption]

State and district where coal was produced	Total used	States where coal was consumed—in order of importance
Alabama.....	4, 460, 630	Alabama and Tennessee.
Colorado:		Colorado.
Trinidad.....	410, 276	Do.
Walsen.....	46, 349	Do.
Crested Butte.....	45, 420	Do.
Canon.....	3, 863	Do.
Illinois: Franklin County.....	90, 964	Illinois.
Kentucky:		
Eastern Kentucky:		
Elkhorn.....	1, 977, 957	Indiana, Michigan, New York, Kentucky, Missouri, New Jersey, Minnesota, Ohio, Illinois, and Wisconsin.
Harlan.....	3, 537, 860	Indiana, Illinois, Michigan, Ohio, and Minnesota.
Kenova-Thacker ¹	1, 233, 550	Michigan, Ohio, Wisconsin, Minnesota, Massachusetts, and Illinois.
Miscellaneous Eastern Kentucky.....	464, 432	Indiana.
Pennsylvania:		
Central Pennsylvania, high-volatile.....	9, 814	New York.
Central Pennsylvania, medium-volatile.....	600, 920	New York and Pennsylvania.
Central Pennsylvania, low-volatile.....	1, 253, 509	Pennsylvania, New York, and West Virginia.
Connellsville.....	13, 591, 861	Pennsylvania, Ohio, West Virginia, New York, Illinois, Minnesota, Michigan, and Indiana.
Freeport.....	1, 668, 909	West Virginia, Michigan, Ohio, New York, and Indiana.
Pittsburgh.....	9, 714, 685	Pennsylvania, New York, Ohio, Minnesota, Illinois, Massachusetts, Michigan, West Virginia, and Wisconsin.
Somerset.....	364, 234	Pennsylvania and West Virginia.
Westmoreland.....	895, 406	Pennsylvania, Maryland, and New York.
Tennessee.....	87, 915	Tennessee.
Utah: Carbon County.....	218, 594	Utah.
Virginia: ^{1 2}		
Southwestern Virginia.....	237, 493	New Jersey, New York, Massachusetts, and Pennsylvania.
Washington: Pierce County.....	47, 129	Washington.
West Virginia: ²		
Northern.....	2, 470, 451	Pennsylvania, Maryland, Ohio, and West Virginia.
Kanawha and Logan (including Coal River).....	7, 961, 107	New York, Illinois, Massachusetts, New Jersey, Ohio, Indiana, Michigan, Pennsylvania, Connecticut, Wisconsin, West Virginia, Rhode Island, Kentucky, Minnesota, and Missouri.
New River and Winding Gulf.....	1, 878, 355	New York, Massachusetts, New Jersey, Illinois, Rhode Island, Missouri, Kentucky, Minnesota, Indiana, Michigan, and Pennsylvania.
Pocahontas ²	10, 076, 552	Indiana, Ohio, New York, Michigan, Illinois, Maryland, Wisconsin, Pennsylvania, Minnesota, West Virginia, Connecticut, Massachusetts, Kentucky, Alabama, and Tennessee.
Coal and Coke.....	112, 904	Pennsylvania.
Webster County.....	316, 803	Pennsylvania and Massachusetts.
	63, 777, 942	

¹ Tonnage from the Grundy field, Buchanan County, Va., is included under Kenova-Thacker (Kentucky).

² Coal from the extension of the Pocahontas field in Tazewell County, Va., is included under West Virginia (Pocahontas).

TABLE 22.—Source of coal used in the manufacture of byproduct coke in 1936, by States where consumed, separating merchant and furnace plants

State where coal was used	Coal produced in—									Total
	Alabama	Colorado	Illinois	Kentucky	Pennsylvania	Tennessee	Utah	Virginia	Washington

Included under "Undistributed."

Yield computed by dividing the production of breeze at the few plants reporting by the quantity of coal charged at these plants.

¹ As reported; quantity produced but not used was undoubtedly greater. See Mineral Resources, 1922, pt. II, pp. 726-727.

CONSUMPTION OF COKE

TABLE 25.—Quantity of coke consumed in manufacture of pig iron and for other purposes, 1913, 1918, and 1934-36, in net tons

Year	Total production of coke	Imports	Exports	Net changes in stocks	Indicated United States consumption ¹	Consumed by iron furnaces ²		Remainder consumed in other ways	
						Quantity	Percent	Quantity	Percent
1913.....	46,299,530	101,212	987,395	(³)	45,413,347	37,192,287	81.9	8,221,060	18.1

1936.....	46,275,184	329,957	670,312	-1,097,318	47,032,147	31,255,648	66.5	15,776,499	33.5

¹ Production plus imports minus exports, plus or minus the decrease or increase, respectively, of the net changes in stocks.

² From Annual Report of American Iron and Steel Institute. Figures include coke consumed in the manufacture of ferro-alloys.

³ Data not available.

TABLE 26.—Pounds of coke and coking coal consumed per gross ton of pig iron made in the United States, 1913, 1918, and 1934-36

Year	Pounds of coke per gross ton of pig iron and ferro-alloys ¹	Percent yield of coke from coal	Calculated pounds coking coal per gross ton of pig iron and ferro-alloys	Year	Pounds of coke per gross ton of pig iron and ferro-alloys ¹	Percent yield of coke from coal	Calculated pounds coking coal per gross ton of pig iron and ferro-alloys
1913.....	2,433.3	66.9	3,637.2	1935.....	1,975.1	69.6	2,837.8
1918.....	2,375.2	66.4	3,577.1	1936.....	2,036.2	70.2	2,900.6
1934.....	2,025.3	69.2	2,926.7				

¹ From Report of American Iron and Steel Institute; the consumption per ton of pig iron only, excluding the furnaces making ferro-alloys, was 1,999.3 in 1934, 1,950.6 in 1935, and 2,006.2 in 1936.

FIGURE 60.—Declining consumption of blast-furnace coke per gross ton of pig iron, 1913-36. The quantity of coke consumed per ton of pig iron has been declining. At the same time, the yield of coke per ton of coal carbonized has increased slightly, so that the consumption of coking coal per ton of pig iron produced has declined from 3,637 pounds in 1913 to 2,901 pounds in 1936.

Anthracite and semianthracite produced outside of Pennsylvania.....	704, 513	350, 068	380, 055	423, 090	450, 000
Bituminous coal for domestic use.....	(⁴)	(⁴)	(⁴)	(⁴)	(⁴)
<i>Oil (barrels of 42 gallons)</i>					
Oil for heating buildings:					
Range oil ⁵	(⁶)	10, 269, 000	15, 756, 000	21, 526, 000	26, 000, 000
Heating oils: ⁷					
Domestic heating.....	5, 021, 000	-----	-----	-----	-----
Commercial heating.....	(⁶)	50, 140, 000	60, 822, 000	76, 853, 000	93, 000, 000
Liquefied petroleum gases, domestic.....	(⁶)	395, 900	421, 000	509, 000	714, 600
<i>Gas (million cubic feet)</i>					
Natural gas consumed for domestic and commercial use ⁸	285, 152	368, 774	379, 497	413, 685	458, 000
Manufactured gas sold: ⁹					
For domestic use.....	(⁶)	223, 110	216, 507	207, 451	204, 007
For house heating.....	(⁶)	20, 037	28, 181	35, 040	42, 430

¹ A considerable part of the Buckwheat No. 1 is used for domestic purposes.

² Partly estimated.

³ Based on figures from Census of Manufactures.

⁴ Between 56,000,000 and 77,000,000 tons a year.

⁵ Range oil is a light distillate used for house heating, hot-water heating, and cooking.

⁶ Data not available.

⁷ Includes all grades of fuel oil used for heating buildings, both houses and offices, hotels, apartments, schools, hospitals, and other large buildings. Includes classifications formerly reported by the Bureau of Mines as "furnace oil", "domestic-heating oil", and "commercial-heating oil." Separation between domestic and commercial heating not available after 1931. (See U. S. Bureau of Mines Mineral Market Report M. M. S. 415, Nov. 19, 1935.)

⁸ Includes gas used for heating offices, hotels, apartments, schools, hospitals, and stores and other large buildings, as well as houses.

⁹ American Gas Association.

STOCKS OF COKE

TABLE 30.—*Stocks of furnace, foundry, and domestic coke and of breeze on Jan. 1, 1937, by States, in net tons*

¹ Gas-house coke is not included.² Data not available.³ Estimate included in total.⁴ Beginning with March 1935, production of the Saar is included with that of Germany.⁵ In Great Britain the production of gas-house coke (including breeze), not included above, is especially important and was as follows: 1933, 11,657,081 tons; 1934, 12,038,825 tons; 1935, 12,181,117 tons.⁶ Figures for 1929 represent "hard" and "soft" coke made at collieries only (73,616 tons of "hard" coke and 769,888 tons of "soft" coke). Data for other years shown represent total "hard" coke manufactured. In addition, the following quantities of "soft" coke were made at collieries: 1933, 837,393 tons; 1934, 874,901 tons; 1935, 904,840 tons.

¹ Includes products of tar distillation conducted by coke-oven operators under same corporate name, except, however, phenol and other tar acids produced at Clairton, Pa.

² Includes gas wasted and gas used for heating retorts.

³ Refined on the premises to make the derived products shown, 163,990,960 gallons.

⁴ Total gallons of derived products.

⁵ Ammonia thiocyanate, asphalt paint, carbolates, cyanimid crystals, cyanogen sludge, ferrocyanide, insecticides, light carbolic oils, pyridine oil, sodium prussiate, spent soda solution, sulphur, and vented vapors.

⁶ Exclusive of the value of breeze production, which in 1936 amounted to \$7,265,615.

FIGURE 61.—Gross value of the several byproducts per ton of byproduct coke produced, 1913-36.

BYPRODUCT-COKE OVENS OWNED BY CITY GAS COMPANIES INCLUDED BY BUREAU OF THE CENSUS IN MANUFACTURED-GAS INDUSTRY

Reference has been made to the byproduct-coke plants installed by city gas companies, which the Bureau of the Census classifies as a part of the manufactured-gas industry and which the Bureau of Mines includes with the byproduct-coke industry. The difference in classification is maintained by the two offices advisedly in the interest of those who can use the statistics. For some purposes the Census grouping is more useful, while for others the grouping used by the Bureau of Mines is the more significant, particularly design of ovens, technique of manufacture, and supply and demand for coal and coke.

To compare or combine the two sets of figures allowance must be made for the difference in classification, which can be done by means of the data in table 50 prepared for the purpose by the Bureau of Mines. The table shows, in parallel columns, separate figures for the byproduct-coke plants operated by city gas companies (grouped by the Bureau of the Census with the manufactured-gas industry) and for all other byproduct-coke plants. Thus, in 1936 there were 21 active plants in the group owned by city gas companies; they produced 3,614,285 tons of coke, 59,153,561 M cubic feet of gas, 49,619,962 gallons of tar, and 3,958,497 gallons of crude light oil. By subtracting their production from the Census figures for the manufactured-gas industry, anyone interested may arrive at the quantities of the several products produced by gas works proper—that is, coal, oil, and water-gas plants.

The table also shows the operations of the 64 plants not owned by city gas companies which were active in 1936. These plants are covered by the Census classification of "Coke, not including gas-house coke, made in byproduct ovens." The figures are compiled by the Bureau of Mines from the reports of the coke producers and are accepted by the Bureau of the Census as an official record of production in the years covered by the Census of Manufactures.

The totals for both groups of plants given in the last column of the table are for the byproduct-coke industry as defined by the Bureau of Mines and given in the other tables of this report.

The first annual review of this series (Minerals Yearbook 1932-33, pp. 433-445) presented the background for the new developments discussed in the subsequent years. Readers unfamiliar with the subject will find it helpful to read this initial review and those following in subsequent yearbooks.

The steady progress of coal research in the United States during 1936 is one of the gratifying features of the uplift from the depths of the depression. Fundamental and applied research in coal technology is now being conducted at a number of centers. Bituminous Coal Research, Inc., reports some 40 laboratories as engaged to some degree in research on coal and coal utilization.¹ At least 10 of these laboratories may be considered major contributors to our knowledge of coal and advances in coal technology. This is a good start, but much remains to be done, as indicated by the report of the Committee on Bituminous Research Planning.²

COMPOSITION, PROPERTIES, AND TESTING

Approval of the Tentative American Standard for classification of coal according to rank and grade³ has provided authoritative boundary lines between anthracite, semianthracite, low-, medium-, and

high-volatile bituminous coals, subbituminous coal, and lignite. Investigations on progressive changes in the properties of coal in relation to rank have shown that the amount of moisture retained ⁴ by typical banded coals, after drying under standardized conditions (25° C. with air of 50 percent relative humidity), and the ease of chemical oxidation ⁵ of the coals, as measured by standard potassium permanganate consumed, increases while the angle of polarization ⁶ of light reflected from polished surfaces of vitrain decreases.

Several publications giving analyses, petrographic composition, and carbonizing properties of North American coals ⁷ and W. A. Bone's comprehensive revision ⁸ of his pioneering book on the constitution and uses of coal were issued in the past year. Hoffmann ⁹ has attempted to correlate the various systems of nomenclature used in coal petrography. Microscopical studies by other investigators have shown that vitrain (anthraxylon) tends to go into the smaller sizes of coal ¹⁰ and fusain concentrates in the fine dust. ¹¹ In several instances, the fusain contained considerably more phosphorus than the associated coals. ¹² Examination of the splint coals of the Upper and Lower Cedar Grove beds of West Virginia indicated that the granular opaque matter which characterizes thin sections of splint coals is derived from coniferous wood fibers. ¹³ Further progress has been made in the correlation of coal beds by identification of spores ¹⁴ and in the "float-and-sink" separation of the banded constituents of coal beds. ¹⁵ About 1 percent germanium has been found in the ash of several Donetz coals. ¹⁶

Pittsburgh bed coal; the close agreement between the properties of corresponding products of the benzene-pressure extract¹⁹ and the residue,²⁰ and of the hydrogenation products²¹ of extract and residue, indicates that these materials are very similar in their essential chemical structure; and it was concluded that the coal structure is made up of fundamental units with an average molecular weight of about 300, held together in larger aggregates by some relatively weak type of linkage.²² These aggregates can be depolymerized or peptized and put into colloidal solution by the action of benzene, quinoline, aniline, anthracene, or certain heavy oils heated under pressure to temperatures well above their boiling points.²³ Such solutions are especially suitable for the production of synthetic gasoline by the hydrogenation process. The various so-called "colloidal fuels"²⁴ are stable suspensions of finely powdered coal in oil rather than colloidal solutions. Russian chemists have identified thioether sulphur as one of the organic sulphur compounds in coal.²⁵

Gas evolution in coal mines.—Mine-air samples taken automatically at 1-hour intervals over 24-hour periods in a number of Belgian mines showed that methane was evolved not only from the face but from fissures behind the face and from the waste. Some seams yielded no methane, whereas others gave off 6,000 cubic feet of methane per ton of coal mined.²⁶ Breyre believes that these large amounts are difficult to explain on the hypothesis of adsorption by the coal, and Audibert,²⁷ on the basis of experimentally determined sorption isotherms of methane in coal at 4° C. and up to 150 atmospheres pressure, concludes that practically all the methane contained in coal is dissolved rather than adsorbed. (See Bureau of Mines Report of Investigations 3233, *The Occurrence of Gases in Coals*, by R. F. Selden, 1934, 64 pp.) Hoffmann²⁸ found that the amount of methane evolved from boreholes decreased with descending rank of coal, and that the amount was greater for dull coal than bright coal in high-rank coals and the reverse in low-rank coals. Leprince-Ringuet²⁹ has summarized recent researches, and others³⁰ have discussed carbon dioxide and methane outbursts.

Spontaneous ignition and effect of low-temperature oxidation.—A Bureau of Mines investigation of the causes of anthracite mine fires found a direct correlation between the spontaneous ignitability of carbonaceous matter and the rate of carbon monoxide formation when the sample was heated in a stream of air.³¹ Studies of the oxidation mechanism and peroxide formation of two hydrocarbons which are components of tars and oils showed that the determination of double bonds in a fuel by means of the bromine or iodine number is not necessarily a measure of self-ignitability.³² For a given bituminous coal, allowed to heat spontaneously in an oxygen atmosphere,³³ it was found that both the rate of oxygen adsorption and temperature rise were nearly linear functions of time, therefore, one may be predicted from the other with considerable accuracy. Mild oxidation of Pittsburgh bed coal³⁴ was found to increase the strength of coke and to decrease the yield of tar very appreciably, long before any changes could be detected in proximate and ultimate analyses, heating value, and agglutinating value. The amount and rate of oxidation increased with descending rank of the coal, and fresh coal oxidized more rapidly than stored coal.³⁵ Treatment of coking coals with oxygen at higher temperatures, up to 300° C., increased the rate of oxidation and the amounts of carbon monoxide, carbon dioxide, and water formed but decreased the amount of oxygen fixed in the coal.³⁶

Plasticity and coking properties.—Measurement of the plastic properties of coal and their relation to coke formation have received considerable attention.³⁷ From observed characteristics of the "transient" fusion of coal, together with its agglutinating index with sand, when coked under specified conditions, Gillet³⁸ claims a satisfactory means of predicting the mechanical properties of the coke to be expected in practice. Agde and Hubertus postulated from numerous extraction and microscopic studies that the colloidal structure of bituminous coal causes plasticity, swelling, and caking.³⁹

Comparison by the Bureau of Mines of the Davis plastometer, Agde-Damm dilatometer, and the Layng-Hathorne gas-flow methods show that the plastometer gives the best data for the plastic range and the dilatometer for the preplastic period. A fairly good prediction of coke quality may be made from the plastometer results.⁴⁰ Others report that dilatometer methods correlate well with the behavior of coals on both low- and high-temperature carbonization.⁴¹

Weathering, admixture of inerts, and variation of rate of heating produces a greater effect on the swelling, plasticity, and rate of decomposition of poorly coking coals than on good-coking coals.⁴² The best cokes are produced from those coking coals which give off the largest amount of gas throughout the plastic range.⁴³ Poor coke may be caused by: (a) A large percentage of volatile matter at the end of the plastic range, and (b) a deficiency of plastic material to bind the coal particles sufficiently to give a nonabradable coke.⁴⁴

Ash fusion and clinkering.—Although the direct determination⁴⁵ of ash-softening temperature is cheaper and more accurate than estimation from ash analysis, investigators continue to obtain data on the relation between the composition of ash and its fusibility.⁴⁶ Combustion tests of anthracite in furnace equipment indicated that ash-softening temperatures corresponding to various degrees of clinker formation were, respectively: 3,000° F., none; 2,810° F., small; 2,450°–2,550° F., bad.⁴⁷ Ash-softening temperatures are functions of compositions in terms of alumina, silica, lime, and ferric oxide on a sulphur trioxide-free basis. These are derived from detrital clay, kaolinite, calcite, and pyrite, as shown by petrographic examination of the separable mineral matter from Illinois and western Pennsylvania coals.⁴⁸

Different types of refractories have been found to have the following relative order of resistance to erosion by coal-ash slags: Forsterite, silica, chromite, magnesite, high alumina (diaspore type), high alumina (electrically fused type), high mullite (bonded type), cast mullite, and silicon carbide, no erosion occurring until the temperature of the refractory face exceeds the ash-softening temperature.⁴⁹ The De-Graaf micropycrometer method has been modified so as to furnish a permanent photographic record of the changes in the coal ash during the fusion interval.⁵⁰

Sampling.—Mechanical methods for the collection of gross samples and their reduction⁵¹ to laboratory size are being more widely used and application of the theory of probability to coal sampling is resulting in a better understanding and interpretation of sampling problems⁵² and laboratory analyses.

Testing methods.—The American Society for Testing Materials⁵³ and the British Standards Institution⁵⁴ have published standard methods for sampling and analyzing coal. The British Fuel Research Station has developed some new formulas for computing "pure" coal analyses,⁵⁵ and German investigators have studied the effect of fusion temperature on ash determinations.⁵⁶

PREPARATION

Increased stripping and mechanical loading activities and more exacting market requirements necessitated further expansion of mechanical cleaning facilities despite further improvement in preparation at the face.^{57 58 59 60 61} A new plant for recovering pyrite and coal from coal-washery refuse, employing ore jigs and concentrating tables, with a capacity of 75 tons of feed per hour, was put into operation at Mineral, Kans. About one-third of the waste from picking tables at Illinois mines can be recovered as marketable coal,⁶² and a central Baum-type jig washery has been erected near Kincaid, Ill., to recover coal and pyrite from picking-table refuse produced at four nearby mines.⁶³ Differences in electrical conductivity and reflecting power of light of coal and refuse are being tried as substitutes for hand picking.^{64 65} Drained high-ash washery sludge, containing 18 percent moisture⁶⁶ and dry dust⁶⁷ from dedusting plants, is used for generating power at mines in Indiana and Illinois. Experimental work in England indicates that the size composition of slack coal, and even of crushed coal, follows the Rosin-Rammler law of size distribution. By means of this law, it is possible to express the size distribution of coal by two numbers instead of the many required in the conventional method of reporting screen analyses.⁶⁸

Dedusting, dewatering, and drying.—At the new cleaning plant of the Bell & Zoller Coal Mining Co., near Zeigler, Ill., which has a capacity of 1,000 tons per hour and uses the sand-flotation cone for coarse coal and pneumatic launder-flow tables for fine coal, the dust is removed during the latter operation and shipped separately or in combination with other sizes. The Pittsburgh Coal Co. dedusts through $\frac{1}{2}$ -inch pulverizer coal by aspiration after washing and heat drying. The Chicago, Wilmington & Franklin Coal Co. also dedusts pneumatically at 48 mesh and ships this product separately or in combination with other sizes. Dedusting is also being done wet by means of sprays on vibrating screens.

The Willow Grove No. 10 cleaning plant of the Hanna Coal Co. (Neffs, Ohio), the Delta Coal Mining Co. (Carrier Mills, Ill.), and the Roslyn-Cascade Coal Co. (Ronald, Wash.), among others, installed rotary-kiln-type heat-drying plants. The first two installations, although of the common rotary-kiln type, admit the hot gases through louvers around the periphery of the shell. A drier of similar design has been used previously in Sweden for drying charcoal.

In Germany a Government commission reviewed the physical and technical problems encountered in drying coal as bearing on the processes of briquetting, carbonization, hydrogenation, and pulverization.⁶⁹ The Fleissner process for dehydrating lignite by heating with steam under pressure is being used in Germany and Austria.⁷⁰

Flocculation and settlement of solids in washery water.—One American washery is using lime and another is using amylaceous materials as flocculating agents to increase the rate of clarification of washery water. Although coal slurries contain very little material of colloidal dimensions, flocculation may be brought about by lyophilic colloid-type flocculators such as starch and glue, but not by electrolytes. Certain slurries not amenable to such flocculents can be made amenable by prior treatment with very small quantities of wetting agents.⁷¹ Numerous patented flocculating agents are being marketed in England, and considerable research on this problem is being carried out in England⁷² and in Germany.⁷³

Dust-prevention treatment.—Rapid growth occurred in the practice of treating coal with oil, calcium chloride, and other agents to render it dustless.⁷⁴ Experiments in the firing of coals sprayed with oils

indicated that ignition is attained more easily but that too much oil decreases air penetration through the fuel bed; efficiency was about 3.9 percent higher with oiled coal. The Interborough Rapid Transit Co. reported that there is no difficulty in grinding oiled coal for pulverized fuel but that no advantage is gained in ordinary firing operations.⁷⁵

Briquetting.—Quite a number of retail coal dealers handling friable, low-volatile coals have installed “packaged-fuel” or other briquetting plants to dispose of fine coal;⁷⁶ plants also have been built for anthracite fines,⁷⁷ lignite,⁷⁸ and bituminous coal.⁷⁹ The Piersol process of making low-volatile coal briquets by impact without binder is to be tried on a commercial scale at Collinsville, Ill.⁸⁰ In Germany and Austria, the Apfelbeck high-pressure roller press is used for making briquets without binder from brown coal and bituminous coal.⁸¹ Krupp and the Lurgi Co. also have developed a “ring roller” press which subjects the powdered fuel to a pressure of 2,500 atmospheres, making firm briquets without binder. The Canadian Bureau of Mines has published a comprehensive review of history, commercial processes, research, and present status and costs of briquetting in North America.⁸²

COMBUSTION

Theoretical studies.—From a mathematical analysis of fuel-bed reactions, Mayers concludes that the coefficient of heat transfer between the solids of the fuel bed and the air or gas stream, the thermal conductivity of the fuel bed, and the specific rate of the combustion reaction appear to depend almost entirely on the physical characteristics of the fuel bed and will be affected more by the size, size distribution, and porosity of the fuel in bulk than by its chemical characteristics. Ignition temperature and possibly coking reactions are the only properties characteristic of a particular fuel that are important in combustion calculations.⁸³ With the aid of models, Rosin has made extensive studies on the effect of relative motion between fuel, air, and combustion gases on the speed of combustion, both for pulverized coal and for combustion on grates.⁸⁴ Here again, physical considerations, such as size of fuel and turbulence of air current were dominating factors in speed of combustion. New methods of determining⁸⁵ and interpreting the ignition temperatures of solid fuels have been advanced. Furnas⁸⁶ proposes to measure reactivity in terms of the

reaction-rate constants for the two equations: $C + O_2 = CO_2$ and $CO_2 + C = 2CO$; Mayers⁸⁷ suggests that the results of the measurement of the reactivity of carbonized materials to oxidizing atmospheres over a wide range of temperatures can be reported in terms of the two parameters b and E of the Arrhenius expression for reaction rate. An ingenious method for studying the combustion rate of carbon has been developed which involves the microanalysis of small gas samples withdrawn from the carbon surface inside the "film" overlying the carbon, whereby the variation of gas composition through the film may be determined.⁸⁸

Residential stokers.—Sales of small stokers increased considerably during 1936, and the studies sponsored by Bituminous Coal Research at Battelle Memorial Institute⁸⁹ have shown that the two principal characteristics of a coal that determine its performance on small stokers are its caking and coking tendencies and its size range, and these are closely related. Relative total costs of coal, coke, oil, and natural gas, based on tests and survey conducted in Columbus, Ohio, were found to be in the following order: Oil, 177; natural gas, 151; bituminous coal (stoker-fired), 119; bituminous coal (hand-fired), 100; semibituminous coal (hand-fired), 97; coke (hand-fired), 95.⁹⁰ The Anthracite Institute Laboratory has developed a new furnace design in which the usual "combustion space" has disappeared, the combustion being complete within the bed of glowing coals. Further application of water-cooled surfaces in the fuel bed for the prevention of clinkers is being studied.⁹¹

Large power plants.—Improvements in the quality of heat-resisting steel and the purity of feed water have permitted increase of superheated steam temperatures up to 950°–1,000° F., and steam generating pressure up to 2,000 pounds per square inch. Such a plant recently has been completed by the I. G. Farbenindustrie at the Leverkusen works. Pulverized coal is burned under the boilers, and the flue gases are cleaned free from smoke and fly-ash by electrical precipitation. The same effective cleaning of flue gas is done at the new Federal Central Heating Plant, situated adjacent to the fine Government buildings in Washington, D. C.⁹² At the new Fulham power station in London, sulphur compounds are removed from the flue gases with a lime treatment. The slag-tap furnaces, which are designed to remove ash as molten slag, are meeting expectations in the United States and are arousing the interest of German engineers.⁹³ The Trinidad power station of the Texas Light & Power Co. has operated successfully for the past 10 years, using 100-percent lignite in pulverized form. Operating costs are said to have been favorable compared with fuel oil and natural gas during a period when there has

been a very large flush production of each within the State.⁶⁴ Piersol⁶⁵ has reviewed previous methods of smoke determination and has devised a new method, based on measuring the absorption of a standard beam of light with a Weston photronic cell and a galvanometer. He found a direct proportionality between the smoke index and the percentage of volatile matter in the Illinois and West Virginia coals investigated.

Coal-dust engines.—The high thermal efficiency of the Diesel-type engine has continued to interest German engineers in solving the problems of abrasion by the ash of the coal dust⁶⁶ and the introduction of the fuel into the cylinders.⁶⁷ Although extremely fine grinding of brown coal is not considered essential by Schor,⁶⁸ Pawlikowski⁶⁹ proposes to grind especially prepared very low ash coal in a liquid medium until the maximum diameter of the grains of ash-forming material is no greater than the film thickness of the lubricating oil on the cylinder walls. This pulp is then injected into the engine cylinder.

COMPLETE GASIFICATION

The production of carbon monoxide and hydrogen for the synthesis¹ of motor fuels and chemical products has led British and European investigators to study gas-producer and water-gas reactions and equipment with a view to speeding up these processes by increasing gas velocity through the producer,² slagging the ash and operating at higher temperatures,³ enhancing the reactivity of the fuel by adding sodium carbonate,⁴ and enriching the air with oxygen⁵ with⁶ or without increasing the pressure. Experiments in which powdered coke treated with 5 percent sodium carbonate was gasified in a stream of steam-oxygen mixtures led to the conclusion that at 1,000° C. and 5 seconds contact time, practically complete decomposition of steam is obtained.⁷ Impregnation of granular coke with 2 percent sodium

carbonate and passing steam and oxygen, preheated to 700°, through it at atmospheric pressure gave a fuel-bed temperature of 1,070° C. and an oxygen consumption of about 35.5 cubic feet per therm of gas produced.⁸ Increasing the pressure of the steam-oxygen mixture to 20 or 30 atmospheres increased the methane content of the gas to about 15 percent, thus giving a calorific value to the gas, scrubbed free from carbon dioxide, of about 450 to 500 B. t. u. per cubic foot. A semicommercial plant, using this process (Lurgi) on brown coal, has been furnishing town's gas at Zittau, Germany.⁹

Underground gasification.—Results of the much-publicized Russian experiments on the underground gasification of coal have appeared in English.¹⁰ According to the authors, successful exploitation has proceeded underground at the Gorlovka mine (Donetz Basin), since August 1935, producing gas at the face of the coal by means of periodical blows of air with admixture of oxygen up to 35 percent. A typical composition of the gas obtained, in percent, is given as: Carbon dioxide 18, carbon monoxide 15, hydrogen 20, methane 3, and nitrogen 44; heating value, 150 B. t. u. per cubic foot. Water gas was made by alternately blowing with air and steam or steam and oxygen. Other underground gasification plants are to be established at various mines.¹¹

German interest in the encouragement of the use of home-produced automotive fuel is exemplified by several informative reviews¹² of portable gas producers, their efficiencies with various fuels, their use on boats, trucks, and buses, and the problems presented in the purification of the producer gas.

HIGH-TEMPERATURE CARBONIZATION

Continued business improvement is reflected in new oven construction in the United States¹³ and abroad.¹⁴ Demand for domestic coke has grown, and a number of papers have been published dealing with improvement of its combustibility¹⁵ by suitable blending of coals, by lowering the coking temperature, and by the addition of sodium

carbonate, lime, or other activating agents.¹⁶ Addition of sufficient lime to combine with the coal ash and $\frac{1}{2}$ to 1 percent sodium carbonate to the coal before carbonization is said to activate high-temperature coke sufficiently to ignite readily and burn freely in an open grate, but not as well as low-temperature coke. The cost is about 1.8 to 2.5 shillings per ton of coke. It is believed that no damage will be caused to the oven refractories by the alkalies, but continued practical operation is required to prove this assumption. Experimental oven coking tests indicate that the addition of finely ground durain (splint) or fusain to a highly plastic coking coal increases its hardness and size-stability, whereas the addition of coke dust tends to increase the size of coke but lowers its resistance to abrasion.¹⁷ Bureau of Mines tests showed that the shrinkage of coke in the range between 500° and 900° C. was about the same for a number of different coking coals.¹⁸

Purification of gas.—The Koppers two-stage thylox process for liquid purification of gas has been installed at the Belle (W. Va.), plant of the du Pont Co.¹⁹ Forty-five million cubic feet of blue water gas per day are purified to a residual sulphur content of 0.2 grain per 100 cubic feet. A Koppers sodium phenolate purification plant, designed to treat 22,000,000 cubic feet of refinery gas per day at 225 pounds per square inch pressure with removal of 95 percent of the hydrogen sulphide, is being built at Philadelphia for the Atlantic Refining Co.²⁰ Improvements have been made in the operation of the detoxification plant at the Hameln Gas Works. German engineers are not in agreement on the economics of the process.²¹ Bunte²² has developed a new method for study of fouling and revivification of oxide in the dry purification process. It consists in supplying measured volumes of the reactants, hydrogen sulphide and oxygen, to the sample maintained at constant temperature at controlled pressures; the course of the reactions is followed by pressure measurements. The method is adapted to the study of the effect of temperature, moisture content, and alkalinity on the activity and life of the purifying material.

Recovery of benzol and tar.—Sixty pounds of activated carbon and 30,000 pounds of steam per 1,000 gallons of crude light oil recovered

are used at the Beckton Gas Works,²³ probably the largest in the world using active charcoal. Three million gallons of benzol are recovered per annum. Use of activated carbon at other gas works is increasing.²⁴ The direct recovery of tar, involving the spraying of hot tar into hot oven or retort gases and fractional condensation (Cooke process), has been in successful operation at three²⁵ plants of the Manchester Corporation for several years. H. Koppers has adapted the pipe still of the petroleum industry to the continuous distillation of tar. Several German plants²⁶ and one at Beckton, England,²⁷ are being installed. The gas leaving the condensers is hot and contains a large amount of tar fog; the fog is removed by electric precipitators operating at 85° to 95° C.

LOW-TEMPERATURE CARBONIZATION

Foreign developments.—Low-Temperature Carbonization, Ltd., of Great Britain raised its dividend rate from 3.5 to 6 percent²⁸ and completed a 288-retort, 500 tons coal per day "coalite" plant at Bolsover colliery.²⁹ This is the world's largest low-temperature carbonization plant for bituminous coal and the fourth operating on the Parker process. The other three are at Barugh, Doncaster, and East Greenwich (London). The total capacity is about 1,400 tons of coal per day. A process originally developed in America for the distillation of oil shale is being tried by Coal Research Syndicate, Ltd., in a pilot plant capable of carbonizing 70 tons of coal per day, at the Mansfield Colliery.³⁰ The coal is heated in two vertical, firebrick-lined, steel retorts, by downward passage of hot gases produced by burning part of the enriched gases taken off from the base of the retort. After the distillation zone has reached a point about two-thirds of the way down the charge (12 hours after the retort is charged), the air supply is cut off, and the remainder of the charge is carbonized by maintaining gas circulation. None of the 15 or more processes proposed in recent years for the carbonization of mixtures of coal and oil has attained proved commercial success.³¹ Coal & Allied Industries, Ltd., operating the Stephenson-process pilot plant at Seaham Harbor, has failed financially;³² the National Coke & Oil Co., Ltd., which developed the "Cannock or Mitford process" at Cannock and Tipton,³³ has built a larger plant at Erith³⁴ said to have a capacity of 1,000

tons of coal per day; Blümner has proposed a process for the production of colloidal fuel whereby equal parts of coal dust and oil are mixed and heated stepwise to 450° C. under a pressure of 25 to 30 atmospheres. Extraction, pressure cracking, low-temperature carbonization, and distillation take place simultaneously, and high yields of light oil and fuel oil are said to be obtained with but little evolution of gas.³⁵ A national drive for home-produced motor fuels in Germany has created renewed activity in low-temperature carbonization³⁶ and the recovery of primary tar suitable for hydrogenation. Forty-five coke ovens in the Ruhr are being modified for exhausting gas and tar fog as soon as formed to minimize thermal decomposition.³⁷ The rotary retorts developed some 15 years ago have disappeared entirely. The present processes for bituminous coal, as described by Thau, use externally heated, intermittently charged retorts. Two Krupp-Lurgi system experimental plants, of 30 to 40 tons coal per day each, have been installed, one at the Amalie mine near Essen and the other in the Saar. These ovens are made of welded-steel plates and consist of alternating rectangular carbonizing cells and heating flues. The cells containing the coal are about 3 inches wide, 6 feet high, and 6 feet long, tapering to a greater width at the bottom. Local overheating of the steel plates is avoided by having an external combustion chamber and circulating the hot combustion gases in the flues between the cells by means of a blower. Carbonizing time is 4 to 6 hours. The BT, the Berg, and the Hinselmann processes, in which coal is carbonized under pressure, are being tried in small pilot plants. Brown coal always has been carbonized at low temperatures. Two new types of carbonizers, the Giessen and the Lurgi, were introduced after the war. In the former, the dried brown coal is carbonized while descending in a thin stream on the outer surface of a vertical, revolving, corrugated cylinder of special alloy-iron, heated on its inner surface. The distillation gases are not diluted by the combustion gases. In the Lurgi carbonizer, the brown coal is heated by direct contact with hot combustion gases circulated through the charge. Consequently, the distillation gases are diluted with combustion gases, and light-oil recovery is reduced. Some 30 Giessen retorts, each of 150 metric tons raw brown-coal capacity per day, and about 40 Lurgi units of 500 to 600 metric tons each per day are installed or under

construction in Germany at present. The Lurgi process also is suitable for lignite and noncaking bituminous coal, and about 15 units have been erected outside of Germany. In Japan, low-temperature coke has not been able to compete with charcoal as a domestic fuel. It has found some use for blending with coal for the production of metallurgical coke and for making water gas. Four plants have been erected.³⁸ Success in the medium-temperature carbonization of coal in narrow byproduct-type coke ovens led to the construction, at the New Brancepeth Colliery in England, of an experimental battery of narrow ovens following three different designs—Kemp, Lecocq, and Cellan-Jones—which could be operated at temperatures down to 500° C. With the inside oven walls at 600° C., the coking time was 26 hours, and the coke contained about 9 percent volatile matter.³⁹ On account of the long coking time and the low oven capacity, the production costs are estimated to be twice that of high-temperature coke.

American developments.—The Lehigh Briquetting Co., at Dickinson, N. Dak., has increased the capacity of its plant for the carbonization of lignite by the Lurgi process to 60,000–70,000 tons of briquets per annum.⁴⁰ The plant of the Pittsburgh Coal Carbonization Co., at Champion, Pa., using a modified Wisner process, ran continuously during the year, producing about twice as much smokeless fuel ("Disco") and byproducts as last year.

Tar oils as Diesel-engine fuel.—Experiments with variable-compression Diesel engines by the Low Temperature Coal Distillers Association of Great Britain are said to have led to the solution of the problem of lowering the spontaneous ignition temperature of low-temperature tar without lowering the flash point.⁴¹ Experiments at the Bochum Mining School in Germany with various fuels led to the conclusion that the Diesel motor can be run on coal-tar oil when in hot condition, but that 100-percent coal-tar oil does not give complete combustion when the load fluctuates and therefore is not well-suited for mine locomotives. However, a mixture of refined tar oil with 10 percent paraffin oil functioned satisfactorily and gave 29 percent thermal efficiency and higher mileage per gallon than either gas oil or paraffin oil alone. For positive starting in cold weather an addition of 25 to 30 percent paraffin oil was necessary.⁴² It also is possible to use coal-tar fuel for air-cell motors by heating the entering air with a "hot-spot."⁴³

HYDROGENATION AND LIQUEFACTION

The total German capacity for the production of gasoline by the hydrogenation of low-temperature tar, lignite, and bituminous coal was said to be about 800,000 metric tons of gasoline per annum on January 1, 1937.⁴⁴ This production consisted of 300,000 tons (350,000 tons annual capacity) from tar and brown coal at the Leuna plant,⁴⁵ and 150,000 tons from bituminous coal at the Ludwigs-haven plant, both belonging to the I. G. Farbenindustrie; 50,000 tons from bituminous coal by the Hydrierwerke Scholven, A. G., at Gelsenkirchen, Ruhr (ultimate capacity, 125,000 tons);⁴⁶ 150,000 to 170,000 tons each from brown-coal tar by two plants operated by Braunkohle-Benzol A. G., Brabag, one at Bohlen, near Leipzig, the other at Magdeburg.⁴⁷ An important recent development by the Mathias Stinnes Muhlheimer Bergwerke Verein in the Ruhr is the installation, on an industrial scale, of the Pott and Broche process in which equal parts of coal and 50 percent tetralin plus 50 percent phenols are heated at 375°–400° C. for 3 hours under a pressure of about 70 atmospheres, due to gases formed in the process itself. It is designed for the production of 30,000 to 50,000 tons of Diesel motor fuel per annum.⁴⁸ An alternative primary liquefaction process (Uhde) using tar oil as the solvent and coke-oven gas as the source of hydrogen (instead of obtaining hydrogen from the tetralin) is being tested on a pilot-plant scale.⁴⁹ Laboratory studies on the extraction of coal by various solvents indicate that depolymerization, followed by colloidal solution, occurs when an appreciable fraction of the coal is dissolved by solvents such as tetralin or coal-tar fractions; and that liquids of medium dipole moment and dielectric constant produce the most marked solvation.⁵⁰

One hundred thousand tons of gasoline were produced from creosote oil, low-temperature tar, and bituminous coal by the hydrogenation plant of Imperial Chemical Industries at Billingham, England, during the first year of operation, ended May 1, 1936.⁵¹ An experimental plant for the hydrogenation of 1 to 2 tons per day of coal tar

has been operated by the British Fuel Research Station.⁵² In Japan, a plant for the production of 50,000 tons of gasoline per year is being erected by the Chosen Coal Industry Co.,⁵³ another with 20,000 tons capacity is being constructed at Fushun by the South Manchurian Railway, a third of 10,000 tons capacity is being planned by the Japanese Electric Co. in North Sakhalin, and a fourth of 25,000 tons capacity by the Mitsui Co. at North Kiushu.⁵⁴ In France, plants having a combined capacity of 50,000 tons of gasoline per year have been erected at Bethune and Liévin.⁵⁵ The Vallette process⁵⁶ used at Bethune is the same in principle as that employed in England and Germany but differs therefrom in that the large reaction chamber is replaced by a number of small-diameter tubes that are easily renewed. Lignites from the Rhone delta are amenable to hydrogenation at a temperature considerably lower than that required for bituminous coal. The Audibert process is used at Liévin.⁵⁷ The Canadian⁵⁸ and United States⁵⁹ Bureaus of Mines are operating small experimental plants for the continuous hydrogenation of about 100 pounds of coal per day, for determining the hydrogenation properties of North American coals.

Research on hydrogenation.—The Fuel Research Station of Great Britain continues to be the principal source of research papers on coal hydrogenation.⁶⁰ Continuously operating semitechnical-scale plants, having daily capacities of 1 to 2 tons of coal or tar, are used for studies of the effect of such variables as temperature, pressure, catalyst, time of contact, etc. Phosphorus, nickel, chromium, or silican compounds added to the molybdenum catalyst promote its activity for the reduction of phenol to benzol.⁶¹ Laboratory research in various countries has shown that the composition of the coal,⁶² the degree of dispersion, and the nature of the liquid medium greatly affect the hydrogenation process. The best medium for each coal appears to

be its own liquid product.⁶³ In the partial hydrogenation of young coals, spores and cuticles were unchanged; the hydrogenation products of the coals had a pitchy appearance and softened at temperatures well under the plastic range of the original coals.⁶⁴ Russian chemists investigated the effect of various catalysts, temperatures, and pressures on the hydrogenation of primary tars, naphthalene, and tetralin.⁶⁵ The best results on peat tar were obtained with molybdenum sulphide at 200 atmospheres pressure and a temperature of 430°–440° C.⁶⁶ Gasolines were stabilized and completely freed from sulphur by hydrogenation at 440° C. and 20 atmospheres of hydrogen pressure in the presence of molybdenum sulphide and chromic oxide catalysts.⁶⁷ The results of studies⁶⁸ of the composition of hydrogenation products of primary tar and oil showing the percentages of olefins, hydroaromatics, aromatics, paraffins, and their boiling ranges, indicate that different final products such as fuel oil, Diesel oil, or gasoline may be produced according to market demands.⁶⁹ A general review of the year's literature on hydrogenation leads to the conclusion that tar hydrogenation is advanced much farther commercially than coal hydrogenation, due to mechanical difficulties in dealing with solid materials.⁷⁰

SYNTHETIC PRODUCTS FROM GASES

After 10 years of development work, the Fischer-Tropsch process⁷¹ for the synthetic production of gasoline from carbon monoxide and hydrogen has been placed in commercial operation in Germany. The following plants aggregating a total capacity of 115,000 metric

Size of plants.....	961	Production of packaged fuel.....	967
Raw fuels.....	961		

Production of fuel briquets in 1936 amounted to 1,124,973 net tons valued at \$7,043,133 f. o. b. plants. Records of production have been kept since 1907, and the output has exceeded that for 1936 only in 1929 when 25 plants produced 1,212,415 net tons valued at \$9,515,205. Thirty-two plants, the largest number in the history of the industry, were in operation in 1936. Several of the new plants which started operations in 1936 worked only a few months at the end of the year and therefore produced only a small proportion of their probable annual output.

The volume of packaged fuel produced in 1936 was 66,427 net tons, or more than double the production of 1935, and the number of operating plants increased from 25 in 1935 to 48 in 1936. Because of its special form, such fuel is not included in the statistics of the briquet industry which relate to the production of unwrapped briquets only. Developments in the packaged-fuel industry are discussed separately in this report.

Trends in the industry since 1907 are summarized in the following table:

Salient statistical trends in the fuel-briquet industry in the United States, 1907-36

[The statistics in this and the following tables cover all types of briquets and boulets except the cube-shaped types wrapped in paper and sold under the name "Packaged Fuel." Data regarding the latter are given separately on pp. 966 to 968]

Year or yearly average	Production of briquets				Im-ports	Con-sump-tion ¹	Value of product, thousands of dollars	Number of plants in operation	Average output per plant, tons	Average value per ton, f. o. b. plant

¹ Production plus imports; the quantity exported has been negligible.

² Not available before 1912.

³ No record of imports is available before 1919, but the quantity imported prior to that time was negligible.

⁴ Revised.

⁵ Figures cannot be revealed for 1936.

FIGURE 64.—Production and imports of fuel briquets, number of plants in operation, and average price received, f. o. b. plant, 1915-36.

Production.—Production of briquets in 1936 was 1,124,973 net tons, an increase of 264,266 tons or 31 percent over 1935. The three geographical regions shared in this increase, but the greatest gains were made in the Central States (Wisconsin in particular).

Wisconsin is the only State for which production and value can be published without revealing the results of operations of individual companies. The nine plants which operated in Wisconsin in 1936 produced 588,163 tons valued at \$4,178,981, which compares with six plants producing 410,715 tons valued at \$2,986,847 in 1935. Thus, in 1936 this State alone produced 52 percent of the national output and 59 percent of the total value.

Four plants in West Virginia and Pennsylvania (two in each State) produced 331,478 tons valued at \$1,341,218. Other States producing over 20,000 tons and in relative order of importance were Oregon, Missouri, North Dakota, and Massachusetts.

In all, briquets were manufactured in 18 States in 1936 compared with 16 in 1935. The one plant operating in Oklahoma in 1935 was idle in 1936. Three States (Illinois, Indiana, and Michigan) had no production in 1935 but reported a small production in 1936.

Fuel briquets produced in the United States, 1935-36

	1935		1936			
	Net tons	Value	Net tons	Value	Percent of change in—	
					Tonnage	Value
Eastern States.....	309,416	\$1,386,137	351,502	\$1,471,884	+13.6	+6.2
Central States.....	485,010	1,347,542	701,544	4,878,200	+44.6	+40.4
Pacific Coast States.....	66,281	615,449	71,927	683,049	+8.5	+12.6
	860,707	1,547,612	1,124,973	7,043,133	+30.7	+28.6

¹ Revised.

Monthly production.—The manufacture of briquets is highly seasonal, because they are used chiefly for house heating. Output increases rapidly during the late fall months with a maximum production reached during the winter, followed by a decline during the spring and low output in the summer. Maximum monthly production in 1936 was in February, when 209,765 tons were produced, nearly six times the output of the low month—July. It will be recalled that the winter of 1935-36 was especially severe, particularly the month of February in the Middle West and in the East.

Monthly production of fuel briquets in the United States, 1934-36, in net tons

Month	1934	1935	1936	Month	1934	1935	1936
January.....	83,607	133,332	146,469	August.....	38,265	41,674	53,454
February.....	71,767	85,578	209,765	September.....	64,420	74,794	78,889
March.....	55,550	46,165	68,593	October.....	77,896	112,152	129,829
April.....	29,104	45,432	40,870	November.....	83,467	97,393	134,250
May.....	39,692	47,328	45,421	December.....	111,836	118,185	127,610
June.....	22,581	34,334	52,638				
July.....	26,681	24,340	36,986		704,856	860,707	1,124,973

Value.—The total sales value of the briquets manufactured in 1936 was \$7,043,133, f. o. b. plants, a gain of 29 percent over 1935. The gain in total value is due to the 31-percent increase in production. The average value, which was \$6.36 in 1935, declined to \$6.26 in 1936.

The average for the entire industry is of doubtful significance because of differences in cost of raw material, in freight charges involved in delivery of raw fuel to briquetting plants, and in prices of other fuels with which briquets have to compete.

Average value per net ton of fuel briquets produced in the United States, 1934-36

	1934	1935	1936
Eastern States.....	\$4.72	\$4.48	\$4.19
Central States.....	6.54	7.16	6.95
Pacific Coast States.....	9.33	9.29	9.64
	6.07	6.36	6.26

¹ Revised.

The average value for the Eastern States in 1936 was \$4.19 compared with \$6.95 for the Central States. In the Eastern States nearly all the production comes from plants located chiefly in the low-volatile fields of southern West Virginia and in the anthracite region of Pennsylvania, where the price of raw fuel does not involve freight charges. Hence, the f. o. b. price of briquets at these plants was relatively low. In the Central States 84 percent of the production comes from plants at coal docks on Lakes Michigan and Superior. The raw fuel for such plants involves a considerable freight charge.

Technical developments.—Measured by tonnage or by value of production, fuel briquetting is a small factor in the American fuel industry. Nevertheless, it is interesting to note that research and experimentation are in progress to improve the technology of manufacture and to find new uses for raw coal.

Since 1931, the Illinois State Geological Survey, under the direction of Dr. M. M. Leighton, has been carrying on laboratory research to develop a smokeless briquet that could be made from Illinois coals without the use of a binder.¹ The process developed includes pre-heating of the raw coal to drive off moisture and some volatile matter; then pressure is applied by impact to form the briquets. Dr. Leighton, in a written communication dated April 13, 1937, states—

The process developed by Dr. Robert J. Piersol * * * for making smokeless briquets without a binder from Illinois bituminous coals is covered by U. S. Patent No. 2021020 and Canadian Patent No. 358755. Doctor Piersol has developed a new-type briquetting press, with patent applied for, for large-capacity commercial production of briquets according to his process. While no smokeless impacted briquets are being manufactured in Illinois at this time, it seems probable that some coal companies will be operating this process on a commercial scale within the coming year. It is estimated that the production cost will be from \$0.50 to \$1.00 per ton of smokeless briquets.

¹ For details of this research work the reader should consult—Piersol, R. J., *Briquetting Illinois Coals Without a Binder by Compression and by Impact: Rept. of Investigations 31, Illinois State Geol. Survey, 1933, 70 pp.* *Briquetting Illinois Coals Without a Binder by Impact: Rept. of Investigations 37, Illinois State Geol. Survey, 1935, 75 pp.* *Smokeless Briquets; Impacted Without Binder from Partially Volatilized Illinois Coals: Rept. of Investigations 41, Illinois State Geol. Survey, 1936, 30 pp.*

An interesting 100-page booklet entitled "Fuel Briquetting", by R. A. Strong, E. Swartzman, and E. J. Burrough was published early in 1937 by the Department of Mines and Resources, Ottawa, Canada, and sells for 25 cents (Canadian). Any person interested in the technology or economics of the fuel-briquetting industry will do well to consult this up-to-date report. The principal subjects include history of briquetting, processes, binders, equipment, investigations of briquetting in North America, economics of the industry, and an appendix review of patent literature.

Number and location of plants.—Thirty-two plants reported commercial production of briquets in 1936 compared with 29 in 1935. Six new plants started in 1936, while three plants which operated in 1935 were idle in 1936. The new plants are in the Middle West, as follows: Illinois—Alwart Brothers Coal Co. (Chicago), Indiana—The Gem Coal Co. (Indianapolis), Michigan—Scheele Fuel & Supply Co. (Jackson), and Wisconsin—Pugh Coal Co. (Racine), C. Reiss Coal Co. (Green Bay), and Ubbing Fuel & Dock Co. (Port Washington).

The estimated annual capacity (not to be confused with actual production) of the six new plants is about 120,000 tons, whereas the estimated capacity of the three idle plants was about 45,000 tons. In addition to the six new plants in 1936, notices in the trade journals report new plants starting operations early in 1937 at Chicago (South Chicago Coal & Dock Co.²) and at St. Paul (Twin City Briquet Co.³). On the other hand, two plants, one of which is in Boston (American Briquet Co.⁴), were to be dismantled early in 1937.

Briquetting plants operated in the United States in 1936

[Does not include makers of paper-wrapped briquets sold under the name "packaged fuel"]

The success of a briquetting plant depends upon factors such as location, freight rates, accessibility to markets, prices of competing fuels, and cost of raw material. In the following table the production in 1935 and 1936 is grouped according to location of plant with reference to source of supply of raw fuel.

Production of fuel briquets grouped according to location of plants with reference to supply of raw fuel

	Net tons		Change in 1936 compared with 1935	
	1935	1936	Net tons	Percent

¹ 1935—Boston and Fall River (Mass.), Salida (Colo.), Kansas City (Mo.), St. Paul (Minn.), and Omaha (Nebr.); 1936—Boston and Fall River (Mass.), Salida (Colo.), Kansas City (Mo.), St. Paul (Minn.), Omaha (Nebr.), Chicago (Ill.), Indianapolis (Ind.), and Jackson (Mich.).

Size of plants.—In the following table the plants are classified according to their actual annual output. A more definite indication of size would be a measurement of the annual capacity of each plant, but it is difficult to arrive at an accurate method of determining capacity because of seasonal variations in production. Thus some plants operate three shifts per day for 25 or 26 days per month during the winter and only one shift per day for 10 or 15 days per month during the summer. A modifying factor to be considered in studying the following table is the fact that a new plant with large capacity may start operations in November or December, and its output for these few months may be only a small fraction of its annual output in the succeeding year. A conservative estimate of annual capacities for the six new plants which began operations in 1936 would show that 18 plants instead of 15 could have produced more than 10,000 tons in 1936, and instead of 11 plants producing less than 2,000 tons, there would only be 6.

Classification of briquetting plants by size of output, 1934-36

Output, net tons	Number of plants			Output, net tons	Number of plants		
	1934	1935	1936		1934	1935	1936
Less than 2,000.....	8	8	11	25,000 and less than 100,000.....	8	5	4
2,000 and less than 5,000.....	3	2	1	100,000 and over.....	1	4	5
5,000 and less than 10,000.....	3	6	5

Raw fuels.—A wide variety of raw fuels continues to be used, ranging from North Dakota lignite (after carbonization at low temperature) to Pennsylvania anthracite and including low- and high-temperature coke, oil-gas residue, and petroleum coke.

Classification of briquetting plants, by kinds of raw fuel used in 1936

High-volatile.....	2
Semicoke (low-temperature coke or char).....	1
Carbon residue from the manufacture of oil gas.....	1
Petroleum coke.....	6

32

¹ 1 plant using low-volatile coal also reported using breeze of high-temperature coke.

The total quantity of raw fuel briquetted in 1936 was 1,066,570 net tons, of which semibituminous coal was the most important. Fourteen plants used 582,232 tons of low-volatile coal, which represents 55 percent of the total raw-fuel tonnage.

Raw fuels used in making briquets in the United States, 1925, 1929, and 1935-36, in net tons

	Net tons				Percent of total

Binders and recarbonization.—Asphaltic pitch is the binder most frequently used in briquet manufacture. Of the 32 plants active in 1936, 19 used asphaltic pitch exclusively. Of the other plants that used binders, two used starch, water, and asphalt; one briquetting asphalt; one coal-tar pitch and asphaltic pitch; two petroleum asphalt; one aspholeum; two starch; one mixed pitches; and one road oil. One plant that briquetted the carbon residue from the manufacture of oil gas required no binder. One other plant reported that briquets were made from low-volatile coal without the use of a binder. The production of this plant was small, and all sales were local.

One producer recarbonized the briquets to drive off the smoke from the binder. Two others reported partly recarbonizing the briquets.

Classification of briquetting plants, by percentage of binder used in 1936

7 and less than 9 percent.....	10
9 percent and over.....	1
	32

¹ 1 plant uses carbon residue from the manufacture of oil gas, and 1 plant uses low-volatile bituminous coal as raw fuel.

Weight and shape.—Briquets weighing 2 to 4 ounces dominate the market. In 1936, briquets of this size were made at 19 plants and comprised 89 percent of the total production.

Prevailing weight of briquets manufactured in 1936

Total.....	32	1, 124, 973	100. 00

¹ Several plants made briquets of more than 1 size, hence the sum of the items in this column exceeds the total number of briquetting plants.

The type of briquet most frequently reported is pillow-shaped. Of the 32 plants active in 1936, 19 made pillow-shaped briquets, 4 cubes, 3 cylindrical, 2 ovoid or egg-shaped, and 1 trapezoidal. One plant reported making three different shapes—pillow, cylindrical, and ovoid. Another plant made pillow and cylindrical shapes, and still another made oval and rectangular shapes.

Principal expenses and value added by manufacture.—The following table has been prepared from information published by the Bureau of the Census. The Census classification of the fuel-briquet industry includes only those establishments with an output valued at \$5,000 or more, in which briquets are the chief products made. The Census, therefore, excludes briquets produced at petroleum refineries or at city gas works, but the returns are representative of independent briquetting plants. The margin between value of product and principal expenses does not represent all profit, as numerous other unreported charges would also have to be deducted.

¹ Data on salaries paid were not collected in the Census of 1931. The figures used have been estimated from the corresponding returns in 1929 and 1933.

² Estimated on basis of 1933 returns at 22 cents per ton.

³ Not to be confused with profit. Charges for interest, depreciation, taxes, insurance, workmen's compensation, rent, and advertising and all other expenses not itemized above also would have to be deducted.

Distribution.—Briquets are widely used. In 1936 they were produced by 32 plants in 18 States. The product of these plants was shipped to 41 States, District of Columbia, and Alaska and exported to Canada. The largest consumption was in Minnesota, followed by Wisconsin. These two States together consumed 45 percent of the 1936 production.

A large tonnage of bituminous coal moves over the Great Lakes during the summer months and is stored at the head of the Lakes at such ports as Sheboygan, Milwaukee, and Superior, Wis., and Duluth, Minn. During the winter months when the Lakes are closed the coal is reloaded and shipped into the Northwest. The fine coal which results from frequent handling has a lower sales value than the coarse sizes, but a higher-grade product can be made by briquetting, and thus a better realization is obtained. Hence, the largest center of briquet production is in Wisconsin. Briquets apparently find a good market in the cities and towns of Wisconsin and Minnesota.

It is not possible to publish a table showing production and destination of shipments for each producing State, because in many States there are only one or two plants and the results of individual operator would be revealed. However, the movement across State lines can be pictured graphically without revealing any confidential information. Figure 65, showing the centers of production and the destination of shipments in 1928 and 1936 indicates the present widespread distribution of fuel briquets.

*Foreign trade*⁵.—Imports of fuel briquets rose to 20,350 net tons in 1936 but were small compared with the domestic production of 1,124,973 tons. The entire tonnage of fuel briquets was imported from Belgium and entered the State of Massachusetts.

¹ In addition to the countries listed briquets are produced in Canada and New Caledonia, but data of output are not available.

² Data not available.

³ Data for year ended Mar. 31 of year stated.

⁴ Beginning with March 1935, production of the Saar is included with that of Germany.

⁵ From domestic coal only.

⁶ Exclusive of Algeria.

PACKAGED FUEL

Sales of packaged fuel began in a small way in 1932, and by 1935, according to reports furnished to the Bureau of Mines, 25,244 net tons were produced at 25 plants. In 1936, 48 plants were in operation and produced 66,427 net tons. The subject of packaged fuel was discussed at some length in the Minerals Yearbook, 1936, pages 658-661.

Packaged fuel is produced at retail yards, usually from the degradation which results from the handling of the coarser sizes. The packages consist of six cube-shaped briquets wrapped in heavy kraft paper and bound with paper tape, usually carrying the advertising of the retail dealer. All packaged fuel is sold locally. The number of packages in a ton varies according to the size and weight of the cubes and ranges from 116 to 200. The latter figure, indicating a weight of 10 pounds per package, is most popular.

The industry is still in its infancy but apparently is very healthy, judging by the 163-percent increase in production in 1936 compared with 1935.

Perhaps the most significant development in 1936 was the sponsorship of packaged fuel by two important producers of low-volatile coal in southern West Virginia. The White Oak Coal Co. in the fall of 1936 contracted for the purchase of 100 Eberling machines "with exclusive package-producing agreements covering all those sections of Illinois, Wisconsin, Michigan, Ohio, and areas in Kentucky imme-

diately south of Cincinnati, which the Eberling firm had not previously assigned to other users."⁶ The White Oak Coal Co. will lease but not sell these machines to retail dealers, who must use White Oak Smokeless coal.

One other producer of low-volatile coals was reported to be operating packaged-fuel plants.

While most packaged fuel has been made from yard screenings, it is possible that as the demand increases in any locality, the available supply of yard screenings may not meet production requirements. Part of the profits arises from the fact that the worth of low-value yard screenings can be enhanced by packaging. Several producers have used slack purchased in carload lots at the mines, and the trend in the industry is to turn more and more to slack shipped direct from the mines. This will tend to insure uniform quality, particularly where dealers have used degradation products from several types of coal. Slack prices at the mines tend to increase during times of industrial activity, while the financial success of packaged fuel depends upon obtaining a high quality of coal at a low price. Fortunately, another factor in the coal industry may assist. With the increasing use of domestic mechanical stokers there is an increasing demand for small coal (nut and slack) from which minus $\frac{3}{8}$ - or minus $\frac{1}{4}$ -inch fines have been removed. The resultant fine coal (minus $\frac{3}{8}$ -inch) makes an exceptionally good raw fuel for packaging.

Production of packaged fuel.—Packaged fuel was produced in 12 States in 1936, compared with 7 States in 1935. Ninety-two percent of the raw fuel used in 1936 was low-volatile bituminous coal. The following tabulation shows production by geographical areas.

Statistics of paper-wrapped cube-shaped briquets sold as packaged fuel, 1935-36

[The plants and production reported in this table are not included in the preceding tables, which apply to unwrapped briquets only]

¹ 1935—Pennsylvania and Virginia; 1936—Maine, Pennsylvania, and Virginia.

² 1935—Indiana and Nebraska; 1936—Indiana, Illinois, Iowa, Nebraska, and Wisconsin.

³ Production is included under "Undistributed" to avoid disclosure.

The value of packaged fuel, f. o. b. plants was \$505,331 in 1936. Average values per ton were \$8.60 in Eastern States, \$7.31 in Ohio, \$8.18 in Michigan, \$9.15 in Minnesota, and \$6.17 in other Central States (including the one plant in Washington).

The monthly production of packaged fuel is apparently more highly seasonal than the production of fuel briquets; in February, for example, it was nearly 17 times larger than in July. It is not fair to make

comparisons with the last few months of the year when production was running over 10,000 tons because a number of new plants began operating at that time.

PEAT

By F. M. SHORE¹

SUMMARY OUTLINE

Summary.....	Page 969	Uses.....	Page 971
Reserves.....	970	Imports.....	971
Production.....	970		

The production of peat in the United States increased substantially in 1936, according to reports received by the Bureau of Mines from the operators of commercial plants that were active during the year. The total production of peat and peat humus amounted to 46,126 short tons that had a selling value of \$266,883 at the plant compared with an output of 37,060 tons valued at \$199,377 in 1935. In addition to the larger domestic output, imports of peat moss reached the record figure of 75,066 tons, making a total of 121,192 tons of peat available for domestic consumption in 1936 compared with 91,607 in the previous year—an increase of 32 percent.

The larger use of peat by domestic consumers in 1936 apparently bears a direct relation to the general improvement in the economic condition of the country as a whole, including an increased demand for agricultural and horticultural products. It is quite possible, also, that the larger use of peat reflects in some degree a growing appreciation of the beneficial purposes it serves and a wider knowledge of the uses for which it is adapted.

At present the domestic output of peat is chiefly used for soil improvement. Although widely employed as a fuel in various countries of Europe, peat cannot at present compete in the domestic markets with the ample supplies of other higher-grade fuels that are readily available, and no commercial production of peat for use as fuel has been reported in recent years.

Although the present application of domestic peat is relatively small compared with the vast reserves available, it has a wide prospective use as a soil conditioner and is moreover an asset of great potential value for future use, not only as raw material but also in the form of derivative products, such as are now obtained by processing coal.

The record of the progress of the peat industry in this country is outlined in figure 66. The notable increase in the production of peat during the World War period was attributable largely to the shortage and high prices of coal and nitrates; and to the demand for soil improvement to increase the production of food.

The situation in the domestic peat-producing industry in 1936 is indicated by the data herein, which were courteously supplied by producers to cover their operations in that year. Every effort has been made to locate and canvass all commercial operations that

¹ Statistics on quantity and value of peat production compiled by M. Otero of the Bureau of Mines.

produced peat in 1936, and it is believed that the results represent a substantial coverage of the industry. A list showing the names and addresses of operators who reported their production in 1936 to the Bureau of Mines will be furnished upon request to prospective purchasers or others who may be interested.

Reserves.—The United States has extensive reserves of peat, chiefly in the Great Lakes region, in New England, and in the Atlantic and Pacific Coast States. The total peat resources of the country (exclusive of Alaska), calculated on an air-dried basis, were estimated 15 years ago at 13,827,000,000 short tons.² The bulk of the reserves is centered in the States of the Upper Lakes region—Minnesota, Wisconsin, and Michigan accounting for approximately three-fourths of the country's total. Of the Atlantic Coast States, Florida, with about 14 percent of the country's total, has the principal peat reserves. California contains most of the known peat reserves of the Pacific Coast region. Approximately one-half of the States of the Union contain substantial peat deposits, although not all are workable. The deposits vary in composition and characteristics and conse-

FIGURE 66.—Quantity and value of peat production, 1908-36. No data are available for the period 1927-33.

quently in their value for specific uses, due to differences in the plant material of which they are composed, the conditions surrounding their formation, and the stage of their development. The surface area of the peat lands in the United States has been estimated at more than 100,000,000 acres. The vast extent of the country's peat reserves clearly indicates the importance of this natural resource as a national asset of both present and potential economic value.

Production.—The quantity and value of the peat produced in recent years are shown in the following table. The increase of 25 percent in the production for 1936 over that in 1935 is a result of the largest output recorded since the annual canvasses of the industry were resumed by the Federal Government in 1934 after a lapse of 7 years. In addition to the encouraging increase in the output of domestic peat in 1936, the average price per ton realized by producers also made a substantial gain—nearly 8 percent.

1926-----	61, 936	364, 413	1936-----	46, 126	266, 883
1934-----	40, 544	214, 185			

¹ No canvass 1927-33, inclusive.

The output of peat in 1936 was reported by 40 producers operating in 15 States. The largest outputs were reported by New York and New Jersey, followed by Florida, Michigan, and Ohio in the order named. Other States reporting the production of peat in 1936 were California, Colorado, Indiana, Iowa, Maine, Massachusetts, Minnesota, New Hampshire, Pennsylvania, and Washington. Of the tonnage produced in 1936, about two-thirds was peat humus, most of the remainder consisting of reed or sedge peat. A majority of the operations are equipped with machinery for shredding the peat, although at some deposits it is marketed only in the raw state. Five operations produced cultivated peat. Available data at this time are too meager to serve as a basis for predicting the trend of output in the immediate future. However, since the need for soil improvement is large and the growth in population will require increasing quantities of foodstuffs, it is not improbable that the peat resources of the country will be used more extensively in the future than has been customary in recent years.

Uses.—Most of the peat produced in this country is used for soil improvement, as an ingredient of fertilizers and a soil conditioner. In addition to its use for the improvement of soils for the growing of crops, peat also is used for the improvement of lawns and golf courses and in gardens, nurseries, and greenhouses. It is also used for poultry litter and stable bedding, as packing material for plants, fruits, vegetables, and fragile articles, and for insulation. Of the production in 1936, 72 percent was sold for use in soil improvement. Most of the remainder was sold for use as poultry litter. No sales of peat in 1936 for use as fuel were reported.

Imports.—Imports of peat moss in 1936 were the largest ever recorded and represented an increase of 38 percent in quantity and 41 percent in value over the imports in 1935. Most of the imports of peat moss came from Europe which has ample supplies of this valuable type of peat that can be produced at a relatively low cost. Germany and Sweden together supplied about 92 percent of the total imports. Canada also supplies peat moss to this country; and, although imports from that country are relatively small, they increased materially in both 1935 and 1936.

The outstanding feature of the petroleum industry in 1936 was the increase of about 111 million barrels (approximately 10 percent) in the total demand for all oils. Moreover, the volume of both production and consumption exceeded all previous records. The trend of demand has been steadily upward since 1932, and statistics available for the first quarter of 1937 indicate further substantial gains. Each annual addition to the enormous total volume of crude oil required emphasizes the difficulty of developing substitute sources and the desirability of conserving our known supplies.

The following table shows the trend of the demand for all oils since 1929.

Total demand for all oils, 1929-36

[Millions of barrels of 42 gallons]

Year	Domestic demand	Exports	Total demand	Year	Domestic demand	Exports	Total demand
1929.....	940.1	163.1	1,103.2	1933.....	868.5	106.7	975.2

1932.....	835.5	103.3	938.8	1936.....	1,093.2	130.0	1,223.2

The proved oil reserves of the United States were estimated at 13,632 million barrels as of January 1, 1935, in a report prepared by the Committee on Petroleum Reserves of the American Petroleum Institute. A preliminary estimate for January 1, 1937, by the same committee indicated a reserve of 13,063 million barrels. This latter estimate may be subject to later revision upward. Apparently, during the past 2 years additions to proved reserves may have balanced production. To supply current market demands requires an active

¹ Figures for 1936 are preliminary; detailed data with final revisions will be released later.

campaign of drilling and prospecting. New oil and gas wells completed in 1936 totaled 25,166, and the estimated number of producing wells at the end of the year was about 350,000.

Increasing demand and active control of new production in the major producing States resulted in a reasonable balance between supply and demand. The total stocks of all oils were reduced by about 23 million barrels. In considering the significance of this reduction, it should be noted that motor-fuel stocks increased by about 6 million barrels; but, despite this increase, the supply of motor fuel at the end of 1936, measured by the average daily demand for the year, was equivalent to about 46 days' requirements, the same as at the end of 1935. Furthermore, a considerable part of the decline in crude stocks was due to the liquidation of older storage as a result of a favorable market for fuel oils.

The domestic production of crude petroleum approximated 1,099 million barrels in 1936, an increase of 102 million barrels over 1935 and 92 million barrels over the previous peak in 1929. Texas, California, and Oklahoma were the three leading producers in 1936. The combined production of these States represented 77 percent of the total output in 1936, compared with 79 percent in 1935 and 84 percent in 1929. The largest increases in production compared with 1935 were 59 percent for Louisiana and 33 percent for New Mexico. The six member States of the Interstate Oil Compact contributed 66 percent of the total production in 1936.

Crude-oil runs to stills in 1936 totaled 1,068 million barrels and exceeded all previous records, showing an increase of 102 million barrels over 1935 and 80 million barrels above the previous record established in 1929. An increase in the amount of crude refined in the Texas Gulf district from 153 million barrels in 1929 to 233 million in 1936 and an increase in the Illinois-Indiana district from 110 million barrels in 1929 to 148 million in 1936 are the most significant shifts in the location of the refining industry during recent years.

New records were established for both production and consumption of motor fuel. Domestic demand reached 482 million barrels in 1936, or almost 11 percent more than in 1935. The most significant factor was the increase in number of motor vehicles in use; others contributing were the revival of tourist traffic and favorable weather conditions in the latter part of the year. The yield of gasoline from crude declined from 44.2 percent in 1935 to 44.1 percent in 1936 and may be attributed to the increase in demand for heating oils and distillates and to increased losses due to re-forming. The yield of cracked gasoline (22.4 percent) exceeded that of straight-run gasoline (21.7 percent) for the first time. Stocks of motor fuel were about 6 million barrels higher at the end of the year than at the end of 1935, but days' supply on the basis of average daily demand for the year remained almost unchanged. It should be noted, in connection with the seasonal changes in the stocks of gasoline, that the increasing demand for distillates apparently is tending to cause an earlier and larger accumulation of stocks, which must be reduced more sharply in later months of peak demand.

The total domestic demand for fuel oils—gas oils, distillates, and crude used for fuel—was 409 million barrels in 1936, an increase of 12 percent compared with 1935. The refinery production of the lighter oils gained over 25 percent and the output of residual fuel oil about 10 percent. The future production of residual fuel oils will be

influenced by the increase in cracking, the expanding market for lighter distillates, and any increases in the price of crude oil.

The production of kerosene in 1936 amounted to 56 million barrels. Exports totaled almost 7 million barrels, and domestic demand was over 51 million. Production of kerosene attained its peak in 1926, when the total was about 62 million barrels, but the decline in exports has prevented duplication of this record. Domestic demand in 1936, however, was the highest ever recorded. The growth in the demand for range oils and for kerosene to be used as tractor fuel are important factors contributing to the increased use of kerosene.

The domestic demand for lubricants rose from 20 million barrels in 1935 to almost 23 million in 1936, but exports of lubricants changed little. Domestic consumption was about 1 million barrels below the record for 1929.

World production of crude petroleum increased by about 136 million barrels in 1936 and totaled 1,790 million barrels. The United States supplied about 102 million barrels of this advance, with Russia and Venezuela increasing by 8 and 7 million barrels, respectively. Imports of crude into the United States rose slightly in 1936, but exports decreased by more than 1 million barrels. Imports of refined products increased by about 4 million barrels for the year and exports by about 2 million.

The trend of the supply and demand of all oils, 1918-36, is shown graphically in figure 67.

Preliminary.

² Imports of crude as reported to Bureau of Mines; all other imports and exports from Bureau of Foreign and Domestic Commerce.

LEGISLATION AND TAXES

Compared with the 3 previous years 1936 was a period of comparative quiet as far as legislation and regulation of production were concerned. No important oil bills were passed by the Federal Government, and, with the possible exception of Louisiana, no State changed its laws on oil conservation materially. By far the major portion of the task of balancing supply and demand of crude petroleum in 1936 was performed by the various State regulatory bodies, with the participation of the Federal Government mainly confined to cooperation through the Interstate Compact, to enforcement of the Connally law curbing "hot oil" production, and to the continuation of the monthly forecast reports of the Bureau of Mines.

No basic change in organization and functions of the Interstate Compact was effected in 1936. Although overtures were made to some States to join the Compact in 1936, there was no change in the roll of the compacting States, which remained as follows: Texas, Oklahoma, Kansas, New Mexico, Illinois, and Colorado. Perhaps the outstanding instance of cooperation between the Interstate Compact and the Federal Government in 1936 was in connection with the survey to determine the quantities and characteristics of crude-oil stocks.

The Connally bill, banning the movement of illegally produced crude in interstate and foreign commerce, was signed by the President on February 22, 1935, and was to be effective through June 15, 1937. In 1936 most of the Federal activities were centered in the Federal Tender Board, Kilgore, Tex., whose operations were supervised by the Petroleum Conservation Division, Department of the Interior; this Division succeeded the Petroleum Administrative Board on April 1, 1936.

The monthly forecast reports of the Bureau of Mines, which, beginning July 1935, followed the allocation reports of the Federal Agency under the Petroleum Code, were issued throughout 1936 as economic guides for the State regulatory bodies and for the industry. As shown in the following table, actual production generally exceeded the Bureau's estimates; in the main this was because the industry did not reduce gasoline stocks as much as anticipated and because the increase in demand exceeded expectations.

At the close of 1936 the Federal import taxes on crude petroleum and petroleum products were as follows: Gasoline, $2\frac{1}{2}$ cents per gallon; lubricating oils, 4 cents per gallon; crude oil and fuel oil, $\frac{1}{2}$ cent per gallon; and wax, 1 cent per pound. Manufacturers' excise taxes were: Gasoline, 1 cent per gallon, and lubricating oil, 4 cents per gallon. The production and processing tax on crude petroleum was reduced from one-tenth to one twenty-fifth of a cent per barrel. The 4-percent tax on pipe-line transportation charges remained in effect. Except for the reduction in the production and processing tax, no changes were made in these taxes in 1936.

State allowables and Bureau of Mines estimates of required production,¹ compared with actual production, 1935-36

CRUDE PETROLEUM

Supply and demand.—The 10-percent increase in demand in 1936 over the previous year was due primarily to the growth in domestic consumption, particularly of motor fuel and heating oils. Data available for the first quarter of 1937 indicate further substantial increases in consumption, which will require a relatively greater increase in the new supply of crude oil if no further reduction in crude stocks occurs.

The total supply of crude petroleum in 1936 was approximately 1,157 million barrels—106 million barrels above the previous records set in 1929 and 1935. The domestic production of 1,099 million barrels was augmented by imports of 32 million barrels and by a withdrawal of 26 million barrels from crude stocks during the year. Compared with 1935 production increased by 102 million barrels, imports showed no appreciable change, and withdrawals from stocks were 4 million barrels greater.

The total demand for crude petroleum in 1936 equaled the supply, since there was no increase in crude stocks. Exports decreased from over 51 million barrels in 1935 to about 50 million in 1936. Domestic demand reached a new record of 1,107 million barrels in 1936. Runs of crude oil to stills totaled 1,068 million barrels, 80 million more than the previous record in 1929. Transfers of heavy crude to fuel-oil stocks, principally in California, increased to about 16 million barrels; and crude representing fuel consumed in production, pipe-line operation, and losses amounted to 23 million barrels.

The relations between the daily average production of crude petroleum, the total number of oil wells completed, and the average price per barrel of a selected grade of Oklahoma crude petroleum from 1930 to 1936 are shown in figure 68.

—Daily average production of crude petroleum, total number of oil wells completed, and average price per barrel of a selected grade of Oklahoma crude petroleum, 1930-36, by months.

PRICES AND VALUES

The average value of crude petroleum at the wells increased from \$0.97 per barrel in 1935 to \$1.05 per barrel in 1936, according to a preliminary estimate. During the past 10 years this figure has ranged from a high point of \$1.30 per barrel in 1927 to a low of \$0.65 in 1931.

Taking the average for 1926 as 100, the Bureau of Labor Statistics price index for petroleum products was 50.5 in 1934, 51.3 in 1935, and 57.3 in 1936. The index rose from 54.4 percent of the 1926 average for January 1936 to 58.0 percent for December 1936.

The posted price of 36°-36.9° gravity crude in Oklahoma, generally accepted as a standard, advanced from \$1 per barrel on January 1, 1936, to \$1.10 on January 9 and remained at that level throughout the year.

Price changes during the year for selected grades of crude petroleum are shown in detail in the tables that follow, and certain longer-term changes by months from 1930-36 are shown in figure 69.

CONSUMPTION AND DISTRIBUTION

Runs to stills.—A new record was set in 1936 for crude run to stills, with a total of 1,068 million barrels, an increase of 102 million over 1935 and 80 million over the previous peak in 1929. Domestic crude runs contributed most of the increase in 1936, as foreign crude runs showed a gain of only 2 million barrels.

The greatest gains in crude runs, by districts, were 33 million barrels in the Texas Gulf Coast, 18 million in the Indiana-Illinois, 15 million in the East Coast, and 12 million in California. The Texas Gulf Coast district showed the greatest relative gain, from 21 percent of the total in 1935 to 22 percent in 1936. This district, together with Illinois-Indiana, exhibited the most consistent long-term expansion in volume of crude refined. In 1936, daily runs were the highest in September when the average was 3,029,000 barrels per day.

¹ Preliminary.

Distribution.—Important production of crude petroleum is concentrated in a relatively few States. Texas, California, and Oklahoma produced over 77 percent of the national total in 1936 and are credited with 81 percent of the proved reserves in an estimate, as of January 1, 1937, by a special committee of the American Petroleum Institute. This geographic concentration of reserves combined with widespread consumption results in the interstate movement of a very large proportion of either crude oil or its products.

Receipts of crude petroleum at refineries totaled 898 million barrels in 1934, 965 million in 1935, and 1,072 million in 1936. Intrastate receipts of domestic crude represented 56 percent of the total in 1936, while interstate receipts amounted to 41 percent and foreign receipts to 3 percent.

Receipts of crude by methods of transportation in 1936 indicated that 71 percent of the total was delivered by pipe lines, 27 percent by boat, and 2 percent by tank car and truck. The accompanying table shows receipts by methods of transportation for the last 3 years.

Receipts of crude petroleum at refineries, 1934-36, by methods of transportation

[In millions of barrels of 42 gallons]

¹ Preliminary.

Beginning with 1934, statistics are available on receipts of crude petroleum at refineries by States of origin. This movement constitutes the principal factor in market demand. The largest refinery receipts of domestic crude in 1936, 401 million barrels, were from Texas; Oklahoma ranked second with 205 million barrels, followed by California with 191 million, Louisiana with 72 million, Kansas with 60 million, and New Mexico with 30 million.

In considering the market demand for Texas crude oil, as indicated by receipts at refineries, the increase during the last 3 years has occurred in deliveries to local refineries, particularly in the Texas Gulf coast district. Intrastate deliveries increased from about 194 million barrels in 1934 to 236 million in 1936, and deliveries to refineries in other States declined from 171 million barrels in 1934 to 166 million in 1936. Receipts of Texas crude by refinery districts are indicated in the following table:

Receipts of Texas crude by refinery districts, 1934-36, in millions of barrels

District	1934	1935	1936
Texas.....	193.6	203.5	235.8
Louisiana.....	32.0	27.1	29.3
East Coast.....	119.8	116.9	118.6
Illinois-Indiana.....	11.1	10.9	10.2
All other.....	8.1	8.4	7.5
Total receipts.....	364.6	366.8	401.4
Exports.....	20.2	23.5	22.5

Oklahoma crude is widely distributed. In 1936 about 27 percent of the shipments went to local refineries and 73 percent to refineries in other States. Shipments exceeded production because of large withdrawals from storage during the year. Receipts of Oklahoma crude by refinery districts are shown in the table below.

Receipts of Oklahoma crude by refinery districts, 1934-36, in millions of barrels

East Coast.....	6.7	10.1	10.6
Total receipts.....	173.7	189.0	204.7
Exports.....	6.9	7.3	7.6

Receipts of crude at refineries in California amounted to 159 million barrels in 1934, 180 million in 1935, and 191 million in 1936. Since no California crude was refined in other States, these figures represent total domestic receipts. Exports of crude amounted to 11 million barrels in 1934, 17 million in 1935, and 15 million in 1936. A considerable amount of heavy crude is used direct and transferred to fuel-oil stocks. These transfers amounted to over 8 million barrels in 1934, 13 million in 1935, and about 16 million in 1936.

Refinery receipts of Louisiana crude have increased from 31 million barrels in 1934 to almost 72 million in 1936. Deliveries to local refineries represented 34 percent of the total in 1936, and shipments to refineries in the Texas Gulf district amounted to about 45 percent of the total with most of the remainder going to East Coast district refineries. Receipts by refinery districts were as follows:

Receipts of Louisiana crude by refinery districts, 1934-36, in millions of barrels

About 56 percent of the crude oil produced in Kansas was delivered to local refineries in 1936, and the major part of the shipments outside the State went to refineries in Indiana and Illinois. Receipts of Kansas crude by refinery districts were as follows:

Receipts of Kansas crude by refinery districts, 1934-36, in millions of barrels

District	1934	1935	1936
Kansas.....	28.3	32.0	34.6
Illinois-Indiana.....	12.7	18.0	22.0
All other.....	3.0	3.9	3.6
Total receipts.....	44.0	53.9	60.2

The major part of the crude produced in New Mexico is widely distributed to refineries in other States. Receipts at the Gulf Coast district refineries of Texas and Louisiana rose from 6 million barrels in 1934 to 12 million in 1936. Shipments to East Coast district refineries amounted to 6 million barrels in 1934 and 8 million in 1936. The Illinois-Indiana refineries received 2 million barrels in 1934 and 6 million in 1936. Receipts for the last 3 years, by refinery districts, were as follows:

Receipts of New Mexico crude, by refinery districts, 1934-36, in millions of barrels

STOCKS

The downward trend of stocks continued in 1936. The net decrease of 23.3 million barrels in the stocks of all oils in 1936 was due to a decline of 26.5 million in crude stocks. Natural-gasoline stocks increased 0.4 million barrels, and an increase of 2.8 million barrels is shown in the stocks of refined products. The stocks of all oils at the end of 1936 totaled 518.4 million barrels, or about 5 months' supply at the rate of demand prevailing during the year.

Stocks of crude petroleum decreased from 314.6 million barrels at the beginning of 1936 to 288.2 million at the end of the year. Producers' stocks increased by about 0.5 million barrels, pipe-line and tank-farm stocks decreased by 24.6 million, and refinery stocks decreased by 2.4 million.

During the year stocks of domestic crude decreased 4.7 million barrels in California and 20.1 million east of California, while stocks of foreign crude declined by 1.6 million barrels.

The most significant changes in crude stocks, on the basis of State origin, were decreases of 13.3 million barrels for Oklahoma crude, 9.0 million for Texas crude, and 4.7 million for California crude, and increases of 3.5 million for Louisiana crude and 2.0 million for New Mexico crude. The decreases represented liquidation of surplus and older stocks, and the increases were incident, in part, to increasing production and demand.

Increases in motor-fuel stocks included about 5.8 million barrels of finished gasoline, 0.4 million of natural gasoline, and of 0.5 million of unfinished gasoline. These increases were about in proportion to increased demand for motor fuel when measured in terms of days' supply.

Stocks of crude petroleum, natural gasoline, and refined products at the end of the year, 1932-36

WELLS

Drilling again gained materially, 25,166 completions (18 percent more than in 1935) being recorded in 1936. Data on the number of producing wells at the close of 1936 are not available, but indications are that the total will increase from 340,990 on January 1 to about 350,000 on December 31, 1936.

Of continued interest was the decrease in the ratio of failures. (See fig. 70.) Although the number of dry holes increased from 4,911 in 1935 to 5,296 in 1936, the percentage of total completions declined from 23 percent in 1935 to 21 percent in 1936. This ratio was the lowest in nearly 20 years.

FIGURE 70.—Wells drilled, 1930-36, by months.

Although drilling in 1936 declined 42 percent from 1935 in the East Texas field the field still continued to lead all others in total footage by a wide margin. There were actually more completions in the Bradford-Allegany field in 1936 than there were in East Texas, but 723 of the Bradford-Allegany completions were water wells drilled under the five-spot program. The little known Loma Novio field of south Texas ranked third in completions. Other areas that were actively explored by the drill in 1936 were Young County, Tex.; Lea County, N. Mex.; and the Fitts and Rodessa fields.

PRODUCTION

In the first 7 or 8 months of 1936 the production of crude petroleum kept pace with the demand for gasoline, the total output showing a more or less steady increase during that period. The daily average production in January 1936 was 2,865,000 barrels, in April the 3,000,000-barrel mark was passed, and in August the daily average reached 3,067,000 barrels. In the closing months of the year the demand for gasoline declined, because of the usual seasonal influences, but crude runs to stills showed little change in anticipation of an active fuel-oil demand. This situation, combined with the pressure of shut-in production to find a market, prevented the late-season decline in crude-oil production that was the characteristic trend prior to the last 2 or 3 years. Production accordingly continued to increase in the last quarter of the year, and the highest daily average output—3,150,000 barrels—was recorded in December.

* Mississippi, Missouri, Tennessee, and Utah.

Production increased in 1936 in all of the major districts except Lima-northeastern Indiana-Michigan. The Gulf coast district, comprising parts of both Texas and Louisiana, showed the largest percentage gain in output in 1936 of any of the districts. The production of Pennsylvania grade crude, which accounts for nearly three-fourths of the output in the Appalachian district, totaled 27,072,000 barrels in 1936, an increase of 6 percent over 1935.

FIGURE 71.—Production of crude petroleum, 1935-36, by States.

Texas retained its rank as the leading producing State, although its share in the national total was slightly less than in 1935. Oklahoma's share increased slightly from the low point of 1935, but California produced somewhat less than 20 percent of the total in 1936 compared with nearly 21 percent in 1935. The loss in percentage accounted for by the three leading States was more than compensated by gains in Louisiana and New Mexico. Louisiana, with a 59-percent gain in production in 1936, passed Kansas to take fourth place among the producing States.

The relative rank of the producing States is shown graphically in figure 71.

Despite a decline in production in 1936, the east Texas field easily retained first place among the producing pools. Oklahoma City, Seminole, and Kettleman Hills retained second, third, and fourth places, respectively. The new entries into the list of the 10 leading fields in 1936 were Rodessa and Fitts, displacing Conroe and Pecos County (mostly Yates), Tex.

Production of crude oil in leading fields in 1936, in barrels

Arkansas.—Arkansas was one of the few States in which drilling declined in 1936; only 24 oil wells were brought in in 1936 compared with 40 in 1935. The downward trend in production, which began in 1925, continued in 1936. The output for the year was 10,419,000 barrels compared with 11,008,000 barrels in 1935.

Exploratory results were generally negative, discoveries being limited to one small, shallow field called Troy in Nevada County; a small, fairly deep field (4,200 feet) in Miller County; and a deep discovery at Snow Hill, Ouachita County, in what is generally called the Permian lime. The Snow Hill discovery looked promising when first found, but producers subsequent to the discovery proved both small and erratic.

California.—Voluntary proration, which broke down in California in the summer of 1935, was restored early in 1936; nevertheless, the State output rose from 207,832,000 barrels in 1935 to 214,773,000 in 1936. Under the curtailment program for 1936, a uniform allowable of 540,000 barrels daily was established in February. This was approximately the actual demand at that time, but increases in demand, seasonal and otherwise, were such as to permit an actual production well over the allowable, plus a substantial withdrawal from stocks.

Although the number of oil wells brought in increased from 729 in 1935 to 792 in 1936, the total initial declined from 660,980 barrels to 374,002 barrels. This decrease reflected principally the declines in pressure in the Kettleman Hills and Mountain View fields.

No sensational gains in output were made in any of the fields in 1936. Kettleman Hills, Ventura Avenue, and Dominguez gained materially, Santa Fe Springs more than held its own, but Long Beach declined.

New discoveries were more in evidence in 1936 than for several years. Five new fields were discovered—Greeley in Kern County, Padre-Canyon in Ventura County, Santa Maria Extension in Santa Barbara County, Ten Section in Kern County, and Wilmington in Los Angeles County. Of these, the first two appeared the most promising as the year closed. Both were seismograph discoveries, indicating the increasing reliance being placed in geophysics in maintaining reserves.

¹ American Petroleum Institute.² Central Committee of California Oil Producers.³ Lost Hills includes Belridge.⁴ Included under "Other."

Colorado.—The production record for Colorado in 1936 was similar to that in 1935, in that the total for the State increased, largely because of a gain in the Iles field. The total output rose from 1,560,000 barrels in 1935 to 1,674,000 in 1936. Of the total, Iles accounted for about 70 percent.

What has been characterized as the most important discovery in Colorado since Moffat in 1923 was the finding of oil in the Tertiary (Eocene) on the Powder Wash structure in the northwestern corner of the State. This was the first Tertiary oil found in the Rocky Mountain district. The Gramps field in Archuleta County, discovered in 1935, was considerably extended, but market conditions prevented commercial production.

Illinois.—Illinois figured more prominently in the oil industry in 1936 than at any time since it was the third ranking producer, about 30 years ago. The greater interest resulted principally from the active leasing campaign of the major companies in the southern half of the State, secondarily from increased activity in drilling and the use of secondary-recovery methods in the older fields. One new field, Bartelso, was discovered. The production rose from 4,322,000 barrels in 1935 to 4,445,000 in 1936, the increase nearly compensating for the decline in 1935.

Indiana.—Although most of the drilling in Indiana in 1936 was for gas, the number of oil wells brought in rose from 37 in 1935 to 45 in 1936. Production, which had declined in 1935, rose from 777,000 barrels to 798,000 in 1936.

Kansas.—Production in Kansas reached a new high in 1936 with a total output of 58,329,000 barrels, an increase of about 3,500,000 barrels in comparison with the 1935 total. Field work also increased, and 1,214 oil wells were completed in 1936 compared with 890 in 1935. Although the ratio of dry holes continued to be above the national average, the percentage of failures in wildcat operations was remarkably low, and numerous discoveries were made. The number of new fields found in 1936 may be placed anywhere between about 35 and 70, depending on how they are eventually connected with older areas. The exploratory work extended over most of the State, even in the old stripper area in eastern Kansas, but most of the new discoveries were in Ellis, Rice, and Russell Counties. Of considerable geological interest was the discovery of flush production in the Viola lime in Reno County.

The Burrton pool continued to lead in production in 1936, with substantial gains in the prolific Silica pool of Rice and Barton Counties and in the Oxford pool of Sumner County.

¹ Oil & Gas Journal.² Included in "Other."

Kentucky.—Production continued to increase in Kentucky in 1936, following a material gain in drilling. Most of the successful completions were in the new Livermore pool of McLean County, which yielded nearly a million barrels in 1936 compared with a few thousand barrels in 1935. This gain offset natural declines in the older pools, and the State total rose to 5,628,000 barrels from 5,258,000 in 1935. Although field work continued to center in the western counties, the old eastern area was the scene of considerable repressuring.

Louisiana.—As already indicated, Louisiana followed her substantial increase in output in 1935 with an even larger gain in 1936. Most of the increase in 1936 was made at Rodessa, but the coastal area continued its rapid rise in importance.

Activities in the Rodessa field overshadowed all other developments in northern Louisiana in 1936. The number of oil wells completed in the field rose from 31 in 1935 to 285 in 1936 and the production from 1,353,000 barrels in 1935 to 19,039,000 in 1936. The output in the older fields was generally lower in 1936 than in 1935, even though several important finds were made at Sligo and other places in the Glen Rose and the deeper Travis Peak formations.

Production from the coastal district of Louisiana established a new record in 1936, the total of 52,877,000 barrels being nearly 30 percent higher than the previous record of 1935. Most of the fields increased their production over 1935, the gains in the Caillou Island, New Iberia, Black Bayou, and Sulphur fields being notable. Production at Iowa declined, but the field was the leading producer in the district in 1936, as in 1933, 1934, and 1935.

Development in the coastal fields in 1936 was characterized by deep drilling, a number of 10,000-foot wells being completed. The exploratory work resulted in the discovery of five new fields—Charenton, Cankton, Valentine, South Jennings, and Bayou Mallet—and extensions or new sands in at least a dozen of the older pools.

Michigan.—Production in Michigan in 1936 suffered its first setback in 5 years, the total output for the year being 11,828,000 barrels, or nearly 4,000,000 barrels less than in 1935. This decrease resulted mainly from rapid declines in the Porter and Crystal fields. Furthermore, the total initial of the 338 oil wells completed in 1936 was hardly more than a third of the total initial of the 322 oil wells completed in 1935.

Wild-cattling was fairly successful, and several new fields and extensions were found. Of these, the Buckeye field of Gladwin County seemed the most promising; in fact, by February 1937 it was the chief factor in reversing the trend in the State output, which had been generally downward throughout 1936.

Mississippi.—No commercial production is credited to Mississippi in 1936, as the several oil wells on the edge of the Jackson field were reported as shut down. Field work was confined to gas wells, several of which were completed by the State on its own land.

Missouri.—Production in Missouri continued to be restricted to about 25,000 barrels annually, most or all of which was marketed as fuel oil. Drilling in recent years has resulted in about a dozen producers annually; these have had an average initial production of about 5 barrels.

Montana.—Development work was active in Montana in 1936, and 166 oil wells were completed compared with 131 in 1935. Production continued the upward trend that began with the discovery of the Cut Bank field, the output rising to 5,588,000 barrels, compared with 4,603,000 in 1935.

The most interesting development in Montana in 1936 was the discovery of oil in deep zones on the Baker-Glendive structure, although, from the standpoint of production in 1936 and the immediate future, the extensions made in the Cut Bank field were more important. The Mosser dome near Billings was proved for oil and gas in 1936. Acid treatment of wells expanded and was generally successful in 1936; in fact, the increases in production in older fields like Kevin-Sunburst was due almost entirely to this practice.

New Mexico.—A new record for production in New Mexico was established in 1936—27,185,000 barrels, compared with 20,483,000 in 1935—although production at Hobbs, the leading field, continued to decline. The material gain in output is traceable to developments in the Eunice and Monument fields, where most of the drilling was done. Drilling on the edges of the two fields virtually proved them to be parts of a structure probably surpassing in size that at Hobbs. Four fields were discovered during the year; all but one were in Lea County.

New York.—The upward trend of production in New York was continued in 1936. The total output for the year was 4,663,000 barrels, compared with 4,236,000 barrels in 1935. The increase resulted from expanded activities under the water-flooding program in response to higher prices.

Ohio.—Production continued to decline in Ohio in 1936 coincidental with the failure to find any new fields of importance and the comparative absence of secondary-recovery projects. The total output in 1936 was 3,847,000 barrels compared with 4,082,000 barrels in 1935. In 1936 oil wells completed totaled 343 and the initial 7,060 barrels; in 1935, 299 oil wells were brought in with a total initial of 4,523 barrels.

Oklahoma.—Production in Oklahoma in 1936 totaled 206,809,000 barrels. This was about 21,500,000 barrels above the output in 1935 and the largest annual total recorded since 1930.

Drilling, which had increased materially in 1935, showed an even larger gain in 1936. There were 1,790 oil wells completed in the State in 1936, or about a third more than in 1935. The large number of dry holes drilled during the year, 649, attests the intensive efforts to find new reserves. The most active area in drilling was Pontotoc County, in which the Fitts pool is located. Other leading counties in field activity were Osage, Seminole, and Oklahoma.

Both Oklahoma City and Seminole, supposedly on the down grade as producers, registered small increases in output in 1936 over 1935. Production at Oklahoma City was sustained largely by the development of the Capitol extension, and at Seminole by drilling inside locations and by reworking old wells. The largest increase in production in any field was at Fitts, which yielded about 20,000,000 barrels in 1936 compared with 7,000,000 in 1935. Other notable gains in output were recorded in the South Burbank, Keokuk Falls, Olympic, and Edmond pools.

Although numerous discoveries were made in Oklahoma in 1936, most of them were extensions laterally or vertically in old fields. Many of the discovery wells had surprisingly large initials but comparatively small drainage areas. Listed as important were the discovery of Wilcox-sand production in the Moore pool, substantial production in the Hunton lime at Fitts, and the extension of the Olympic field. Attempts to find deep Ordovician pools had little success.

¹ Oil and Gas Journal.

* Included under "Other."

Pennsylvania.—Total production in Pennsylvania in 1936 was 17,070,000 barrels, compared with 15,810,000 in 1935. Although most of the increase was recorded in the water-flood areas of the Bradford field, which yield nearly half the State output the other districts (Kane-Butler and Southwest) showed surprisingly large gains in production. This was due primarily to the successful application of secondary methods, although deeper drilling in the Oriskany in Washington County is reported to have been quite fruitful.

Tennessee.—Although production in Tennessee continued to be virtually negligible at 10,000 to 20,000 barrels annually, the higher prices for crude renewed interest in drilling, and several of the old areas were being explored for deeper production at the close of 1936.

Texas.—Production in Texas in 1936 rose to a new record of 427,280,000 barrels—about 9 percent higher than in 1935. As in 1934 and 1935, all the gain was outside of the East Texas field; in fact, all the other major districts gained in 1936.

The State is so large and production so scattered that it is customary to discuss developments in Texas by districts. No two of the half dozen or more agencies dealing in production statistics divide Texas into the same districts. This suggests the possibility of a joint conference in the interests of uniformity; but, pending such action, the Bureau's districts will remain essentially as follows: Panhandle, including counties north of a line drawn from the southern boundary of Collin County to the southern boundary of Deaf Smith County; West Texas, including all counties south of the Panhandle and west of a line drawn southward between counties from the east boundary of Childress County to the east boundary of Maverick County; North Texas, including counties east of the line just described, west of Fannin, Hunt, and Van Zandt Counties, and north of a line drawn from the south boundary of Runnels County to the south boundary of Kaufman County; East Texas, for which the inside border counties are Fannin, Hunt, Van Zandt, Henderson, Anderson, Houston, Trinity, Polk, Tyler, Jasper, and Newton; South Texas, including Dimmit, LaSalle, McMullen, Live Oak, Webb, Duval, Jim Wells, Zapata, Jim Hogg, Brooks, Starr, and Hidalgo Counties; and Central and Gulf districts, separated by a line dividing Bee and San Patricio Counties on the southwest, Colorado from Wharton and San Jacinto from Liberty, with Montgomery included in the Gulf. The only change made in these districts in the past year was the transfer of Zavalla and Frio Counties from the South (formerly Southwest) Texas district to Central Texas.

Although production in the Panhandle increased slightly in 1936, the district passed a relatively quiet year. No new oil fields were discovered; and, except for one dry hole carried beyond 8,000 feet, wildcatting was at a low ebb. The production for the year was 22,471,000 barrels compared with 21,369,000 in 1935. The number of oil wells completed declined from 585 in 1935 to 466 in 1936.

Production in the west Texas district continued to increase parallel with the growth in general interest in the area. Production increased from 55,417,000 barrels in 1935 to 61,901,000 in 1936, while the number of oil wells completed more than doubled, rising from 653 in 1935 to 1,369 in 1936.

Production at Yates (the leading field of the district) declined, but material gains were made in Ward County and in the Cowden, Sayre and Goldsmith fields. The latter, particularly, proved to be large.

About six or eight new fields were discovered in the west Texas district in 1936, and several new counties produced for the first time. The district was enlarged considerably, particularly on the north, although extensions in the older fields probably had more influence on production. Among the new discoveries, the following seemed to be the most important: Bennett, Yoakum County; Henderson, Wilkier County; and Seminole, Gaines County.

Apparently both production and drilling in the north Texas district were stimulated by higher prices and showed small gains over 1935. New discoveries were few, as the area has been explored carefully for surface indications and as considerable territory has been condemned by tests to the granite. Most of the fields suffered a natural decline in output, increases in Jones, Cooke, and Jack Counties being outstanding. The most important discoveries for 1936 appeared to be a pool near Bryson, Jack County, and the Anderson-Kerr (Bruhlmeier) pool near Gainesville in Cooke County.

Production and bottom-hole pressures in the east Texas field proper continued to decline in 1936, but neither caused great concern, as the output is still severely prorated and as bottom-hole pressures generally decrease as the oil is withdrawn. The output for the year was 168,046,000 barrels from producing wells ranging in number from 19,520 on January 1 to nearly 22,000 at the close of 1936. Bottom-hole pressure at the end of the year was 1,168 pounds, or only 25 pounds below the pressure on January 1. Drilling in the east Texas field in 1936 was virtually confined to inside locations, the number of oil wells brought in declining from 4,033 in 1935 to 2,335 in 1936. The average size of the new completions continued to decline, the average in 1936 being 1,150 barrels daily initial compared with an average of 1,590 barrels in 1935.

Although completely overshadowed by the east Texas field, the Van field continued in the select circle of pools that produce more than 10,000,000 barrels annually. Its output fell from about 14,000,000 barrels in 1935 to about 13,000,000 in 1936, but the decline was due entirely to reduced allowables.

The Rodessa field was known to extend into Texas in 1935, but development did not get under way until 1936. Production from about 160 wells in 1936 was 3,091,000 barrels, compared with only 12,000 barrels in 1935. Apparently most of the field will be in Texas eventually.

Another active field was Cayuga, where about 60 oil wells were completed in 1936. A second deep test to the Trinity was drilled at Cayuga in 1936—it was a distillate producer at 7,570 feet.

The district remained a popular section for wildcatting, and with reason, as several important discoveries were made. Most important of these were the Talco field of Titus and Franklin Counties and the Sulphur Bluff field of Hopkins County. These are fault-line pools in the Lower Cretaceous. Several other discoveries were made, but they were distillate producers.

The number of oil wells completed in the South Texas district, formerly called Southwest Texas, in 1936 was about 1,400, or double the number completed in 1935. Most of the drilling was confined to inside locations in the Loma Novio, Lopez, and Seven Sisters fields. Increased production in those fields outweighed declines in the older fields, and the total output of the district accordingly rose from about 13,000,000 barrels in 1935 to about 19,000,000 in 1936.

Wildcatting was not quite as extensive or as successful in 1936 as in 1935, the half dozen or more new productive spots appearing to be of little importance as the year closed.

Comparisons for the Central Texas district are hard to draw, as no two sets of data cover exactly the same fields; however, apparently the "fault-line" or Edwards lime area passed another relatively quiet year in 1936, with production virtually unchanged and with few discoveries. The only new fields brought in were Zoboroski in Guadalupe County and Pearsall in Frio County.

The success that has attended exploratory work in the Texas Gulf Coast district in recent years was evidenced in production, which continued to establish new records in almost every month of 1936. The total output for 1936 was 86,283,000 barrels, compared with 64,914,000 in 1935.

Conroe, the leading producing field of the district, again dropped in output, undoubtedly reflecting adjustments in allowables rather than inability to produce to the 1935 level. Important gains in production were scored in the Saxet, Greta, Anahuac, and Plymouth fields.

Approximately 25 new discoveries were made in the district in 1936, most, perhaps all, as the result of geophysical prospecting. Among the new fields with the most promise were Amelia, Jefferson County; Flour Bluff, Nueces County; and Heyser, Calhoun County.

Utah.—No developments of importance were recorded in Utah in 1936, and the production remained virtually unchanged from that of 1935 at 12,000 barrels.

West Virginia.—Although field activity increased materially in 1936, most of the work was concerned with outlining new gas reserves, and no new oil pools were found. The number of oil wells completed rose from 115 in 1935 to 142 in 1936, but production declined from 3,902,000 to 3,847,000 barrels.

Wyoming.—Drilling increased materially in Wyoming in 1936, 88 wells being completed compared with 58 in 1935. Production at Salt Creek showed a small decline, but this was more than offset by material gains at Lance Creek and the comparatively new fields of Medicine Bow and Quealy. The State production in 1936 was 14,455,000 barrels—700,000 barrels more than in 1935. The largest factor in this increase was the completion of large wells in the Sundance at Lance Creek; in fact, black-oil production and light-oil production outside of Lance Creek together declined approximately 500,000 barrels. Apparently the most important discovery of the year in Wyoming was the finding of a prolific Tensleep zone at Wertz, an old gas field.

¹ Includes Ferris.

² Included under "Other."

³ Garland includes Byron.

⁴ Includes Iron Creek and Simpson Ridge.

⁵ Includes Simpson Ridge.

REFINED PRODUCTS ¹

A record for refinery operations was established in 1936. Crude oil run to stills amounted to 1,068,000,000 barrels compared with 988,000,000 for 1929, the next highest year, and with 966,000,000 for 1935. Motor fuel and kerosene production and demand reached new peaks, while the gas oil and fuel oil demand, which has been gaining for several years, increased 12 percent during 1936 to 409,000,000 barrels, still 40,000,000 barrels short of the 1929 record.

The yield of fuel oil—38.5 percent compared with 37.3 percent for 1935—is the highest since 1930 and indicates the increased demand for the lighter fuel oils for heating purposes; the yield of the latter rose 1.4 percent, while the yield of the heavy fuel oils fell 0.2 percent. Part of this advance was at the expense of kerosene, the yield of which dropped 0.5 percent. Although the yield for motor fuel decreased only 0.1 percent—from 44.2 percent in 1935 to 44.1 percent in 1936—it probably would have increased along with increased cracking in some districts had it not been for the strong demand for heating oil.

Natural gasoline blended amounted to 42 million barrels in 1936 compared with 39 million in 1935; and benzol increased 36 percent, from 1,871,000 barrels in 1935 to 2,537,000 in 1936.

The total refinery output of gasoline in 1936 was 513 million barrels, made up of 231 million barrels of straight-run gasoline, 240 million barrels of cracked gasoline, and 42 million barrels of natural gasoline; the quantity produced by cracking still gaining faster than straight-run production. Kerosene production amounted to 56 million barrels, the same as in 1935. Gas-oil and distillate fuel-oil production increased 26 percent, to 126 million barrels in 1936 from 100 million in 1935; and residual fuel oil increased to 286 million barrels from 260 million in 1935.

Analysis of production and consumption of petroleum products in 1936 ¹

¹ Preliminary.² Based on total gasoline production less natural gasoline used.**MOTOR FUEL**

Demand.—The domestic motor-fuel demand of 481,591,000 barrels in 1936 is an increase of 10.8 percent over the former high record of 434,810,000 barrels—that for 1935. The most significant factor in this higher motor-fuel demand was an increase of 2 million automobiles in motor-vehicle registrations, which is reflected in a slightly smaller advance in motor vehicles in use. Although the motor-fuel demand per motor vehicle rose about 0.90 barrel in 1936—from 17.81 to 18.71 barrels per vehicle—the increase during the past few years has not been as large as might be expected from the combined influence of the trend and recovery, indicating that the trend is not increasing at as rapid a rate as heretofore.

FIGURE 72.—Trends in production, domestic demand, exports, imports, and stocks of motor fuel, 1918-36.

The number of motor vehicles in use on July 1, 1936, is estimated as 25,643,000, compared with 24,294,000 on the same date in 1935. Both of these figures are based upon preliminary estimates of registrations, and the 1936 figure is also based upon the estimated number of cars scrapped, as these statistics cannot be calculated until information on the 1937 registrations is available. This increase of 1,349,000 is to be compared with an advance of 811,000 from 1934 to 1935 and of 738,000 from 1933 to 1934.

¹ Natural gasoline losses not included.² Least squares straight-line trend based on 1924-31 data. Depression years have been omitted because they are not normal.

Although it is often difficult to account for the fluctuations from month to month, extreme weather conditions in 1936 showed their influence on gasoline consumption. The gasoline temperature index (an index computed by weighting the temperature deviations from normal in the various parts of the country by the gasoline consumption) was 6.1° below normal for February, the greatest minus deviation for any month in 12 years, and the motor-fuel demand was about 4 percent below normal. The gasoline temperature index for December was +3.1°, the highest plus deviation for any December during the past 12 years, and the demand was about 8 percent above normal. While there were probably other factors besides weather that entered into the abnormally high demand for this month, it is safe to assume that mild weather, combined with the holiday season, had a material influence upon gasoline consumption.

¹ Preliminary.

Distribution of motor-fuel demand by uses must be estimated. The figures for bus use are based upon a study made by the Bureau of gasoline consumption by busses (Information Circular 6639). The proportion of highway and city gasoline consumption was determined from mileage studies by the Bureau of Public Roads. The trends in proportion of traffic on the highways were determined from traffic over toll bridges, and the trends in the proportion of traffic in cities were determined from traffic surveys.

1936.....	481,501	428,600	14,500	150,885	170,116	321,001	35,460	57,639	93,099

Production.—The 515,485,000 barrels of motor fuel produced in 1936 comprised 231,287,000 barrels of straight-run gasoline, 239,620,000 barrels of cracked gasoline, 33,817,000 barrels of blended natural gasoline, 8,224,000 barrels of unblended natural gasoline, and 2,537,000 barrels of benzol. The ratio of straight-run gasoline to total motor-fuel production continued its decline from 48.8 percent in 1934 and 46.9 in 1935 to 44.9 in 1936. The ratio of cracked gasoline, on the other hand, continued to increase in comparable proportions, rising from 43 percent in 1934 and 44.3 in 1935 to 46.5 in 1936. The ratio of natural gasoline declined from 8.4 to 8.2 percent, while the proportion of benzol remained 0.4 percent. The decline in the proportion of natural gasoline probably reflects the tendency to use still gases to obtain lighter-volatility gasoline instead of natural gasoline.

The increase in gasoline production from 458 million barrels in 1935 to 505 million in 1936 was distributed among the various districts, as the accompanying table shows. The most significant gain was in the Texas Gulf district, which produced 14,807,000 barrels more in 1936 than in 1935; this was 32 percent of the increase for the whole country and represents a gain of about 17 percent for that district. Although the Louisiana Inland-Arkansas district produced 36 percent more in 1936 than in 1935, production in 1935 had declined considerably from the previous year, and the 1936 production is only 15 percent above that of 1934. Texas Inland and Indiana-Illinois, with increases of 13 and 12 percent, respectively, were the next most important districts. The Appalachian district declined slightly, and the gain in the East Coast district was only 3 percent.

The last two columns of the table indicate the trends of production in the various districts at the end of the year. The average monthly

production in the Texas Inland, Indiana-Illinois, Texas Gulf, Rocky Mountain, and Louisiana Inland-Arkansas districts was 9 to 10 percent higher during the last 3 months of the year than for the whole year, while the change for California and Louisiana Gulf was negligible.

¹ Preliminary.

The average yield of gasoline in 1936 was 44.1 percent of crude run to stills compared with 44.2 percent in 1935 and 44.7 percent in the peak year of 1932. The yield of cracked gasoline for the first time exceeded that of straight-run, being 22.4 percent compared with 21.5 percent in 1935. The yield of straight-run gasoline declined to 21.7 percent from 22.7 percent for 1935. This represents a decline of almost 3 percent from the 1931 high of 24.6 percent. The increasing percentage of cracked gasoline and the declining percentage of straight-run gasoline is due to the re-forming or cracking of straight-run gasoline to obtain higher antiknock values; this is evidenced in the failure of the total yield to increase, due to losses in re-forming. Combined with this as a cause for keeping the total yield low was the strong market for heating oil, which demanded material that otherwise would be used for cracking stock.

This effort to supply the heating-oil market was quite evident in the east-coast district, where the yield dropped from 41.7 percent in 1935 to 39.6 percent in 1936. The average yield for the last 4 months of 1936 was 38.6 percent as against 43 percent for the same period of 1935. The yield in the Appalachian district, continuing a trend of several years, fell from 48.6 percent in 1935 to 47.5 in 1936, although this trend reversed itself during the last half of the year. Both Inland Texas and California showed an increase in the percentage yield from cracking, which raised the total percentage yield for the former district from 48.2 percent in 1935 to 50.2 in 1936, and for the latter district from 32.5 percent in 1935 to 34.3 in 1936.

Prices.—Although the average refinery price of regular-grade gasoline in Oklahoma was 5.60 cents for 1936 compared with 5.37 cents for 1935, gasoline prices as a whole did not improve during the year. The price at the beginning of the year was 5.63–5.75 cents and, coincident with the crude-oil price increase, rose in the second week in January to 6.13–6.25 cents. In the first week of February prices began to drift off, reaching a low for the year of 4.88–5.38 cents in September and October, from which they recovered to 5.13–5.38 cents in December.

On April 15, 1936 the regular grade of 63–70 octane gasoline was changed to 63–67 octane, and a new grade of 68–70 was added, probably accounting wholly for the price being lower at the end of the year than it was at the beginning, as in other grades the prices for the two periods were the same.

Gasoline prices, 1932–36, in cents per gallon

² American Petroleum Institute.

The average A. P. I., 50-city, service-station price ex tax rose from 13.55 cents per gallon in 1935 to 14.10 cents in 1936. The largest change came during January, when the average price increased from 13.70 cents on January 1 to 14.26 cents on February 1, coincident with the increase of 10 cents per barrel in the price of crude oil. The February average price was the highest of the year, the increase of 0.24 cent per gallon for crude oil not being able to support the increase of 0.55 cent per gallon for gasoline; and declines during March brought the April 1 average to 13.85 cents, the lowest for the year except that for January. These declines, except that for Dover, Del., where the price dropped 2 cents on March 19, occurred in the western part of the United States. Gasoline prices dropped 3 cents in Reno, Nev., 2.5 cents in Seattle, Wash., Portland, Oreg., San Francisco, Calif., and Phoenix, Ariz.; and 2 cents in Denver, Colo. The price average recovered to 14.23 cents by May 1 and varied from that but slightly until the seasonal winter decline brought it to 13.96 cents in November and December. During December price increases in several cities brought the average to 14.13 cents by the end of the month.

The price was highest in Twin Falls, Idaho, where the rate of 25 cents per gallon, including a 6-cent tax, prevailed throughout the year. Next in order were Boise, Idaho, which opened the year with a price of 24.5 cents; Montgomery, Ala., 24 cents; Helena, Mont., and Birmingham, Ala., 23.5 cents; and Butte, Mont., Atlanta, Ga., and Pensacola, Fla., 23 cents. Billings, Helena, and Great Falls, Mont., all closed the year with a price of 24.5 cents.

The lowest price at the beginning of the year was at Los Angeles, where gasoline sold at 15.5 cents, including a 4-cent tax, while the price at San Francisco was 16.5 cents. On March 3 the price was reduced to 13.5 cents in both cities until April 1, when the cut was restored, and the price was 17.5 cents in Los Angeles and 18 cents in San Francisco at the end of the year. In Providence, R. I., where the price at the beginning of the year was 16 cents, including a 3-cent tax, gasoline sold for as low as 14.5 cents during part of October and November and closed the year at 15.3 cents, the lowest in the country.

The average tank-wagon price for 1936 was 12.62 cents per gallon, 0.6 cent higher than the average for 1935. The price ranged from a low of 12.11 cents on January 1 to 12.80 during the summer months and was 12.54 cents on December 1. The differential between the average service-station and the average tank-wagon price for 1936 was 1.48 cents, compared with a differential of 1.53 cents for 1935.

State gasoline tax rates ranged from 2 cents per gallon in Missouri, Rhode Island, and the District of Columbia to 7 cents in Florida, Louisiana, and Tennessee, in addition to a Federal tax of 1 cent per gallon plus various municipal and county taxes. The tax rate was increased from 5 to 7 cents per gallon in Louisiana on July 28, while it was decreased from 4 to 3 cents per gallon in New York on July 1. At the end of the year there were 2 States and the District of Columbia with a tax rate of 2 cents, 11 States with a tax rate of 3 cents, 17 States with a tax rate of 4 cents, 9 States with a tax rate of 5 cents, 5 States with a tax rate of 6 cents, 1 State with a tax rate of 6½ cents, and 3 States with a tax rate of 7 cents.

Stocks.—Motor-fuel stocks, including stocks of gasoline at refineries, at bulk terminals, and in pipe lines and stocks of natural gasoline amounted to 60,408,000 barrels on December 31, 1936, compared with 54,345,000 barrels on the same date in the previous year. The quantity of motor fuel on hand at the end of 1936 was 45.91 times the average daily demand during the year compared with 45.62 for the motor fuel on hand at the end of 1935. Early in the year, when the demand for fuel oil necessitated heavy runs to stills and excessive gasoline production, stocks began to increase out of proportion to the usual seasonal gain, reaching a peak of 71,681,000 barrels at the end of March, from which they declined to a low of 55,793,000 barrels at the end of October.

The largest increase was in the Gulf Coast district, where the gain of 2,213,000 barrels represented 37 percent of the total. California was next, with an increase of 1,666,000 barrels—27 percent of the total.

Consumption by States.—Figure 73 shows the gasoline consumption by States. New York used more gasoline than any other State again in 1936, having consumed 40,996,000 barrels (9 percent of the total for the United States). Other important consuming States were California, with 39,371,000 barrels (8 percent); Pennsylvania, 30,556,000 barrels (7 percent); Illinois, 28,379,000 barrels (6 percent); and Ohio, 27,807,000 barrels (6 percent). The demand of these five States represents 35.8 percent of the total United States demand in 1936 compared with 36.1 percent in 1935.

FIGURE 73.—Gasoline consumption, 1935-36, by States.

Consumption of gasoline, 1919-36, by States and years¹

(Thousands of barrels of 42 gallons)

[The figures represent quantities of gasoline sold or offered for sale, as reported by wholesalers and dealers in the various States under provisions of the gasoline-tax or inspection laws. Such laws were not in operation in all States prior to 1930.]

The only States where consumption was less than in 1935 were Nebraska, North Dakota, and South Dakota. Consumption in North Dakota in 1936 was 7 percent less than in 1935, when it was 17 percent above the level in 1934, the greatest gain made by any State. Wyoming was again one of the States to show a large increase, the gain this year being 19 percent compared with 13 percent in 1935. In New Mexico consumption was 22 percent greater than in 1935. Increases of approximately 18 percent were registered in Arizona, Alabama, and Tennessee. It is likely that a large part of the apparent increase in Tennessee represents more efficient tax collections rather than an actual gain in consumption.

Distribution.—There were no motor-fuel imports in 1936, and exports declined from 30,613,000 barrels in 1935 to 27,831,000 in 1936, continuing the downward trend that was interrupted by war buying in 1935.

Exports, by districts and months, are shown in the following table:

KEROSENE

Domestic demand for kerosene continued its upward trend in 1936, amounting to 51,479,000 barrels—3,834,000 barrels more than in 1935. This increase may be attributed to the growth in its use for domestic cooking and heating or as range-oil fuel. The following table shows the annual kerosene demand from 1931 to 1936:

Domestic demand for kerosene, 1932-36

[Thousands of barrels of 42 gallons]

Year	Range oil	Other uses	Total	Year	Range oil	Other uses	Total
1932.....	6,841	26,380	33,221	1935.....	21,526	26,119	47,645
1933.....	9,849	28,644	38,493	1936.....	26,000	25,479	51,479
1934.....	15,756	28,478	44,234				

¹ Estimated.

Exports of kerosene total 6,886,000 barrels, slightly more than the 6,651,000 barrels exported in 1935. The percentage yield of kerosene declined for the second successive year to 5.3 percent from 5.8 percent in 1935. Although the domestic demand for kerosene increased 3,834,000 barrels in 1936, production increased only 269,000 barrels—from 55,813,000 barrels in 1935 to 56,082,000 in 1936, the difference being drawn from stocks, which declined from 7,915,000 barrels to 5,633,000 during the year.

The tank-wagon price for kerosene at Chicago, which remained at 9.8 cents per gallon from May 1935 to March 1936, rose during the last week of that month to 10.1 cents and remained at that figure throughout the summer. It dropped to 9.2 cents on September 1 but recovered to 9.5 cents on the first of December, where it stayed for the rest of the year. The average refinery price of kerosene increased for the fourth consecutive year, averaging 3.85 cents for 1936 compared with 3.70 cents for 1935.

GAS OIL AND FUEL OIL²

In 1936 it was necessary to increase substantially the production of both light and heavy fuel oils to meet consumer requirements. The refinery output of fuel oils in 1936 was 411,338,000 barrels compared with 360,061,000 in 1935, a gain of 14 percent. The above figures include fuel oil produced by cracking, totaling 225,857,000 barrels in 1936 and 194,734,000 in 1935. This is the third consecutive year in which fuel oil from cracking stills has exceeded the quantity obtained from straight-run refinery operations. In providing this larger amount of fuel oil in 1936, crude runs to stills were augmented by 11 percent, or from 965,790,000 barrels in 1935 to 1,068,134,000 in 1936. The crude runs yielded 125,650,000 barrels of gas oil and distillate fuel oil, a gain of 25 percent over the 1935 total of 100,235,000 barrels, and the production of residual fuel oil was higher by 10 percent, totaling 285,688,000 barrels in 1936 compared with 259,826,000 in 1935. The increase in percentage yield of gas oil and distillate fuel oils from 10.4 percent in 1935 to 11.8 percent in 1936 indicates a readjustment of refinery runs to meet the heavy demand for heating oils. The percentage yield of residual fuel oils changed but slightly, showing 26.9 percent in 1935 and 26.7 in 1936.

Calculations from known factors show an indicated domestic demand for fuel oils of 408,991,000 barrels in 1936, including 15,732,000 barrels of crude oil transferred to fuel oil in California. This was an increase of 12 percent over the 1935 indicated domestic demand of 366,723,000 barrels, including 13,067,000 barrels of crude oil transferred to fuel oil in California. The distribution of the 1936 demand by principal consumers is only partly known at present. Records compiled by the Interstate Commerce Commission show that class 1 railroads, in 1936 purchased 60,216,000 barrels of fuel oil, including Diesel oil, compared with 54,323,000 barrels in 1935. According to the Federal Power Commission, public-utility power plants required 14,119,000 barrels of fuel oil in 1936, a gain of 24 percent over the 1935 total of 11,393,000 barrels. Slightly less bunker oil was required by vessels engaged in coastwise trade in 1936. This loss, however, was more than made up by the bunker oil demand of vessels in the foreign trade, which increased sufficiently to give a net gain of 1,689,000 barrels in the 1936 bunker-oil loadings.

After the known items of demand in 1936 are deducted, a balance is left to supply all other fuel-oil needs, that totals 277,617,000 barrels compared with a balance of 245,657,000 barrels in 1935. Heating oils consumed in 1936 probably represented one-third of the 1936 quantity, and the difference was available for other major users, such as manufacturing industries, oil companies (field and plant use), the gas-manufacturing industry, the United States Navy, and other Government departments. These other demands, of which the respective volumes are unknown at present, comprise over 75 percent of the increased or new consumption in 1936 (31,960,000 barrels of a gain of 42,268,000 barrels of new demand in 1936). Indications point to a large increase in the use of heating oils in 1936, but the extent of the gain by other major users cannot be gaged at this time.

Imports of fuel oil and gas oil into Continental United States totaled 19,135,000 barrels in 1936 compared with 16,130,000 in 1935. Most

² By A. T. Coumbe, Petroleum Economics Division, Bureau of Mines.

of this foreign fuel oil is credited to the Netherland West Indies, with Mexico and Canada as secondary sources of supply. The import trade is confined largely to bunker oil received in bond for the supply of vessels, with New York the principal port of entry. Bunker oil received under this classification totaled 17,005,000 barrels in 1936, a gain of 5,232,000 barrels over 1935.

Exports of fuel oil and gas oil and shipments to noncontiguous territories, which totaled about 29,000,000 barrels for both 1934 and 1935, showed a gain of 18 percent in 1936 when 34,280,000 barrels were shipped out of the country. This is still well below the peak of 47,384,000 barrels of fuel oil exported in 1927. The 1936 gain over 1935 is shown in both light and heavy fuel oils. Gas oil and distillate fuel oils exported and shipped to noncontiguous territories totaled 19,884,000 barrels in 1936 compared with 16,249,000 barrels in 1935; and exports of residual fuel oils totaled 14,396,000 barrels in 1936, a gain of 1,697,000 barrels. Exports of fuel oil and gas oil to Japan, the principal foreign buyer, decreased slightly in 1936, when the total was 9,256,000 barrels compared with 9,292,000 in 1935. The gain in exports of fuel oil and gas oil must be credited largely to such European countries as Germany (2,841,000 barrels in 1936 compared with 843,000 in 1935), Netherlands (1,741,000 barrels in 1936 compared with 1,010,000 in 1935), and Italy (1,689,000 barrels in 1936 compared with 949,000 in 1935).

Fuel-oil stocks, which have declined since 1929, rose in 1936. Total stocks of fuel oil increased from 103,984,000 barrels at the end of 1935 to 106,918,000 at the end of 1936. Virtually all of this gain was in the gas oil and distillate fuel oils, stocks of which increased 2,789,000 barrels out of a total gain of 2,934,000 barrels. This accumulation of light fuel-oil stocks was centered mostly in California, where the increase was 1,983,000 barrels compared with 806,000 barrels in all other parts of the country. Heavy or residual fuel oils held in storage in California also increased noticeably, showing a gain of 4,254,000 barrels during 1936. The demand for heavy fuel oils in the other sections of the country was so pronounced that it was necessary to draw 4,109,000 barrels from storage, so that the net build-up in residual fuel oils for the country as a whole was only 145,000 barrels.

Fuel-oil prices in 1936 trended slightly upward. A weighted average price for 1936, compiled by Joseph E. Pogue, is \$0.918 compared with \$0.892 in 1935. Bunker C fuel oil at New York was advanced three times during the year due to the pressure of an almost record demand coupled with a tightening of the available supply and higher charter rates. On January 1 the New York price of Bunker C was increased by 10 cents to \$1.05 per barrel, and the same relative increase was put into effect at all other Atlantic and Gulf ports. A 5-cent increase effective August 17 brought the New York Bunker C price to \$1.10 per barrel, and a similar advance was made at most ports north of Charleston, S. C. Diminishing stocks of heavy oils in the eastern area of the country, brought about by continued heavy demand, forced still another general 5-cent-per-barrel increase effective October 1. The New York price for Bunker C was raised to \$1.15 per barrel, and a like advance was posted at other Atlantic ports. Ample supplies of heavy fuel oil in the Pacific area helped to prevent much of a price increase. However, Bunker C at Los Angeles was slightly higher in 1936, averaging \$0.9227 per barrel compared with \$0.8993 in 1935.

A strong demand for light fuel oils was met by an ample supply, so that price increases were not as pronounced as with the heavier grades. An example is no. 2 straw distillate fuel oil, which averaged 3.1174 cents per gallon in 1936 compared with 3.0229 cents in 1935 at Oklahoma refineries.

The following tables show pertinent statistics covering the distribution of gas-oil and fuel-oil sales, by major uses and by States, in the order of importance for the years 1930-35. A study of the items covering the distribution by uses brings out the fact that the low point in demand by various classes of consumers was reached in different depression years, ranging from 1931 for heating oils to 1934 for ships' bunkers and U. S. Naval use. The demand for heating oils has advanced steadily since 1931 and in 1935 became the principal item displacing bunker oil for the first time. The fuel-oil requirements of manufacturing industries have gained steadily since 1932, so that in 1935 the total of 61,128,000 barrels approached the peak demand of 63,431,000 barrels recorded in 1929.

The table covering the sales of gas oil and fuel oil by States, in order of importance, for the years 1930-35, shows California as the most important consumer with a 1935 total of 70,631,000 barrels, a quantity equal to about one-fifth of the national demand and almost equal to the combined demand of Texas and New York, which rank second and third in importance as fuel-oil markets. After California and Texas, where railroad, ships' bunkers, and oil-company use are largely responsible for the volume of demand, the fuel-oil market shifts to the north Atlantic seaboard to the densely populated States of New York, New Jersey, Pennsylvania, and Massachusetts, where the demand for heating oils, ships' bunkers, industrial power, and oil-refinery fuel build up impressive totals in fuel-oil consumption. The fuel-oil demand of Illinois, next in importance among the States, is attributed largely to the requirements for heating oil.

¹ Includes some crude oil burned as fuel.

LUBRICANTS

The domestic demand for lubricants, which was seriously depressed from 1932 through 1935, recovered substantially in 1936. The total demand during the year was 3,015,000 barrels greater than in 1935 and amounted to 22,676,000 barrels, a figure exceeded only in 1928 and 1929. The demand reached a peak of 23,609,000 barrels in 1929. It is estimated that 13,760,000 barrels of the demand in 1936 were used by motor vehicles and 8,916,000 barrels for industrial purposes. The following is the estimated division of the demand for lubricants into motor-vehicle and industrial uses.

Domestic demand for lubricating oil, 1929-36

[Thousands of barrels of 42 gallons]

Year	Con- sumption by motor vehicles	By in- dustries	Total domestic demand	Year	Con- sumption by motor vehicles	By in- dustries	Total domestic demand
1929.....	13,429	10,180	23,609	1933.....	11,781	5,371	17,152
1930.....	13,614	7,975	21,589	1934.....	12,337	6,087	18,424
1931.....	13,447	6,621	20,068	1935.....	12,722	6,939	19,661
1932.....	12,061	4,553	16,614	1936.....	13,760	8,916	22,676

Exports of lubricants, amounting to 8,315,000 barrels, were slightly less than the 1935 figure of 8,499,000 barrels.

Stocks of lubricants on hand December 31, 1936, totaled 6,942,000 barrels, compared with 7,025,000 on the same date in 1935. As usual, the East Coast district, with 2,151,000 barrels, compared with 2,227,000 barrels at the end of 1935, had the largest stocks. Gulf Texas ranked second, having 1,350,000 barrels, compared with 1,553,000 barrels in 1935. The figures for both these districts represent the lowest points in long downward trends. The figure for California—1,055,000 barrels, compared with 975,000 barrels in 1935—represents the highest stocks since December 31, 1930. The stocks in the first two districts have dropped from 54 percent of the total at the end of 1935 to 50 percent at the end of 1936, and California's proportion has risen from 14 to 15 percent during this same period.

FIGURE 74.—Trends in prices of refined petroleum products, 1930-36, by months.

Price trends for lubricating oils were not consistent for the various grades in the different parts of the country. Refinery prices for bright stocks in Oklahoma, after showing a 1½-cent increase during the summer, relapsed in November to the price in effect early in the year. Prices for pale neutrals in the Midcontinent field, after holding steady through most of the year, dropped 3½ cents in October and had recovered only 1 cent of this drop by the end of the year. Pennsylvania grades of neutrals, after displaying weakness throughout the year, were about the same or slightly higher in December than in January; Pennsylvania bright stocks gained about 2½ cents during the summer and closed the year 1½ cents higher than in the beginning of the year; and other cylinder stocks gained about 3½ cents during the year.

OTHER PRODUCTS

WAX

The production of paraffin wax amounted to 472,920,000 pounds in 1936 compared with 450,240,000 pounds in 1935. Domestic demand also increased to 301,488,000 pounds from 261,353,000 pounds in 1935, and exports declined to 187,342,000 pounds in 1936 from 229,905,000 pounds in 1935. Imports declined from 19,557,000 pounds in 1935 to 16,669,000 pounds in 1936. Stocks increased slightly to 115,434,000 pounds on December 31, 1936.

The average price in New York for yellow crude scale wax for domestic shipment recovered only slightly from the 1935 decline, the average being 2.4 cents per pound, compared with an average of 2.2 cents in 1935.

COKE

Domestic demand for petroleum coke declined to 1,253,400 short tons in 1936 from 1,340,700 in 1935. Exports declined to 124,300 short tons in 1936 from 133,500 in 1935.

ASPHALT AND ROAD OIL

The domestic demand for petroleum asphalt increased sharply in 1936, amounting to 4,033,400 short tons, compared with 2,845,800 in 1935. Details for asphalt and road oil may be found in the chapter on Asphalt and Related Bitumens.

STILL GAS

The production of still or refinery gas totaled 207,535 million cubic feet in 1936, compared with 197,220 million in 1935.

WORLD PRODUCTION AND FOREIGN TRADE¹

The upward trend in world production of petroleum, first evidenced in the increase in the total for 1933, was continued in 1936, when 1,790,271,000 barrels were produced, compared with 1,654,593,000 in 1935. The largest single factor in the gain of 136,000,000 barrels in world output was the gain of 102,000,000 barrels in the United States. The share of the United States, which fell just under 60 percent in 1934, rose to 60.2 percent in 1935 and to 61.4 percent in 1936.

All the leading producing countries showed gains in 1936, and no important changes in rank occurred. The largest relative gain for any country was registered by Bahrein Island, which produced 4,645,000 barrels, compared with 1,265,000 in 1935.

Data on oil-shale production for 1936 are lacking except for Estonia, whose output apparently showed a material increase over 1935. The 1935 data show Scotland producing more oil shale than all other countries combined, but production in the U. S. S. R. (Russia) was expanding rapidly. No commercial production in the United States has been reported since 1929.

¹ By A. H. Redfield, Petroleum Economics Division, U. S. Bureau of Mines.

¹ Data not available.² Includes some boghead coal.**IMPORTS, EXPORTS, AND SHIPMENTS THROUGH PANAMA CANAL**

The tendencies in the foreign trade of the United States in mineral oils that have been manifested since the middle of 1932 continued in 1936. Although both imports and exports of mineral oils increased in quantity from 1933 to 1936, their relationship to the total demand, domestic and foreign, has remained virtually unaltered. A change in the fiscal policy of the United States reduced both the quantity of mineral oils imported since the middle of 1932 and their proportion of the national supply. Increased production of crude petroleum in other countries has decreased both the quantity and the proportion of all oils exported since 1930, and the growth of refining in other countries has effected a sharp increase in exports of crude petroleum at the expense especially of the lighter refined products.

Imports of petroleum and its products (including wax, petrolatum, and asphalt) into continental United States increased from 52,782,000

barrels in 1935 to 57,250,000 in 1936, according to statistics obtained from the Bureau of Foreign and Domestic Commerce. In 1936 dutiable imports of mineral oils for direct consumption totaled 36,228,000 barrels, compared with 33,596,000 in 1935. Imports in bond, primarily for supplies of vessels and secondarily for refining and export, amounted to 21,022,000 barrels in 1936, compared with 19,187,000 in 1935.

The proportionate increase in imports of petroleum, both dutiable and bonded, from 1935 to 1936 was 8 percent, compared with an increase of 10 percent in total demand, domestic and foreign, over the same period. In terms of daily demand, domestic and foreign, the total imports in 1935 amounted to 17.3 days' supply and in 1936 to 17.1 days' supply. Imports of petroleum and petroleum products constituted about 5 percent of the total national demand for mineral oils, domestic and foreign, in both 1935 and 1936.

As a result of higher excise taxes levied on imported gasoline and lubricating oil, 99.3 percent of the total imports in 1935 and 98.7 percent in 1936 consisted of crude petroleum, fuel oil, and unfinished distillates. Such finished light oils as were imported went chiefly to Puerto Rico and the Virgin Islands.

Increases in imports of dutiable crude petroleum, chiefly heavy crudes from Mexico and Venezuela for the manufacture of asphalt, of fuel oil in bond for the supplies of vessels, and of unfinished oils for further refining were offset in part by decreases in imports of fuel oil into Atlantic coast and Gulf coast ports for domestic consumption.

Crude petroleum imported into and exported from continental United States, 1930-36

¹ Data from Bureau of Foreign and Domestic Commerce.

² Includes imports via Netherland West Indies.

Imports of crude petroleum, both dutiable and bonded, increased 2 percent over 1935 in 1936. Their daily average of 90,000 barrels in 1936 did not exceed the daily average of 91,000 barrels for the 4 years 1933-36 and was less than half of the daily average of 183,000 barrels of crude petroleum imported during the 4 years 1928-31 before excise taxes in the Revenue Act of 1932 were adopted. More than nine-tenths of the foreign crude petroleum received in 1936 consisted of heavy Venezuelan and Mexican crudes imported, duty paid, primarily

for the manufacture of asphalt and road oil. Included in the total imports, however, were 2,391,567 barrels of lighter crude from Venezuela entered for refining in bond and export of the manufactured products. Colombia, which shipped to the United States 13,000,000 barrels a year of 29°-30° crude from 1929 to 1931, supplied only 71,590 barrels in 1936, all for refining in bond and export of the finished products.

Entries of fuel oil into bond, primarily for supplies of vessels, increased from 12,954,000 barrels in 1935 to 18,016,000 in 1936. Included in these totals were 736,000 barrels in 1935 and 852,000 entered into bond in Puerto Rico. The Netherland West Indies supplied 14,676,000 barrels of the fuel oil entered into bond in 1936, Mexico 3,266,000 barrels, and Canada 74,000 barrels. Of the 17,164,000 barrels of fuel oil entered into bond in continental United States in 1936, 16,440,000 barrels were withdrawn from bond for supplies of vessels, 13,000 barrels exported, 164,000 barrels withdrawn from bond for domestic consumption on payment of duty, and 547,000 barrels added to storage. Bonded stocks of fuel oil in continental United States on December 31, 1936, totaled 1,647,000 barrels.

Direct imports of fuel oil and topped petroleum into continental United States for domestic consumption decreased from 7,691,000 barrels in 1935 to 5,336,000 in 1936. To these amounts were added 307,000 barrels of fuel oil withdrawn from bond for domestic consumption on payment of duty in 1935, and 164,000 barrels similarly withdrawn in 1936.

Ninety-three percent of the fuel oil and topped crude, dutiable and in bond, imported into continental United States in 1935 and 94 percent in 1936 went to Atlantic coast ports, and 6 percent in both 1935 and 1936 went to Gulf coast ports.

Imports of paraffin wax listed in the accompanying table included 409,000 pounds in 1935 and 1,022,000 in 1936 entered into bond primarily for reexport.

¹ Bureau of Foreign and Domestic Commerce.

² Includes shipments to Alaska, Hawaii, Puerto Rico, and the Virgin Islands.

At the same time, exports of petroleum, crude and refined, from continental United States and shipments of mineral oils to the non-contiguous territories increased 2 percent—from 128,987,000 barrels in 1935 to 131,245,000 in 1936. These exports and Territorial shipments constituted 12 percent of the total demand for all oils, domestic and foreign, in 1935 and 11 percent in 1936.

The principal increases were in exports and Territorial shipments of gas oil and distillate fuel oil, due primarily to the growing use of Diesel-type engines. Smaller increases were shown in exports and shipments of residual fuel oil, lubricating oils, and kerosene. On the other hand, exports and shipments of gasoline and light fractions of petroleum were somewhat less in 1936 than in 1935, owing chiefly to increased refining activity in Europe, the Netherland West Indies, Canada, Iran, and Japan.

Two-fifths of the exports and Territorial shipments of mineral oils from the United States in 1935 and 1936 consisted of crude petroleum. These decreased slightly—from 51,430,000 barrels in 1935 to 50,313,000 in 1936. In both years nearly nine-tenths of the total shipments were made to three countries. Exports of crude petroleum to France declined from 10,348,000 barrels in 1935 to 7,463,000 in 1936 as a result of greater receipts by French refineries from Iraq, Rumania, Peru, and Venezuela. Exports to Japan were slightly less—10,483,000 barrels in 1935 and 10,394,000 in 1936. Canada, however, increased its purchases of American crude from 24,412,000 barrels in 1935 to 25,683,000 in 1936. Increased shipments of crude to Italy, Argentina, Cuba, Sweden, the Netherlands, and the Union of South Africa aided in offsetting the decline in shipments to France, Germany, and the United Kingdom.

Of the major refined oils, exports and Territorial shipments of motor fuels and of naphtha declined 9 percent—from 30,613,000 barrels in 1935 to 28,544,000 in 1936. These totals included 349,000 barrels of benzol in 1935 and 456,000 in 1936. The greatest decreases were in sales to the United Kingdom, which reduced its purchases from 5,883,000 barrels in 1935 to 4,665,000 in 1936 buying more from the Netherland West Indies, Rumania, and Trinidad in 1936; to France, which decreased its purchases from 2,413,000 barrels in 1935 to 867,000 in 1936 and increased at the same time its receipts from Rumania, Iran, and the Netherland West Indies. Similarly, exports of light petroleum products to Australia, Belgium, Canada, the Philippine Islands, Hawaii, and to Sweden were less in 1936 than in 1935. On the other hand, exports of gasoline and naphtha to the minor foreign consumers increased from 1935 to 1936, but not sufficiently to arrest the decline in shipments to the major purchasers.

Exports and Territorial shipments of kerosene from the United States increased 4 percent from 1935 to 1936. Although shipments to the Netherland West Indies, the United Kingdom, the Netherlands, the Philippine Islands, Sweden, Finland, Panama, and Hawaii increased, exports to Brazil, China, Australia, Portugal, and Norway were less in 1936 than in 1935.

The greatest increase was in exports and Territorial shipments of gas oil and distillate fuel oil—from 16,249,000 barrels in 1935 to 19,906,000 in 1936. The principal gains occurred in shipments to Germany, which has especially fostered the use of the Diesel-type engine, the Netherlands, the Netherland West Indies, Belgium, Spain, and Greece. On the other hand, less gas oil and distillate fuel

oil was sold to Japan, which increased its refinery output, and to the United Kingdom, which bought more from Rumania.

Although international shipping continued to revive, competition of the Netherland West Indies, Mexico, Trinidad, Rumania, Iran, and Netherland India was responsible for the smaller increase in American exports and Territorial shipments of residual fuel oil—from 12,699,000 barrels in 1935 to 14,411,000 in 1936. Increased sales to Japan, Chile, Canada, Italy, Panama, Spain, the Philippine Islands, and Greece, as well as to smaller purchasers, contributed to the general increase, in spite of smaller sales to Mexico, New Zealand, and some minor foreign consumers.

As a result of general economic recovery and of continued industrialization of the less-developed countries, exports and Territorial shipments of lubricating oils increased from 8,499,000 barrels in 1935 to 8,680,000 in 1936. The principal purchasers in 1936 were the United Kingdom, Germany, Belgium, France, British India, Canada, Australia, Japan, Italy, and China, which took, all together, more than three-fourths of the total exports.

¹ Includes exports from noncontiguous territories.

² Includes natural gasoline.

Shipments through Panama Canal.—Shipments of mineral oils from California to the Atlantic coast through the Panama Canal decreased from 9,769,000 barrels in 1935 to 7,992,000 in 1936. The principal decrease was in shipments of gasoline, which formed 73 percent of the total shipments in 1935 and 1936. Lower tanker rates, averaging 39 percent of the rates from California to Atlantic ports, enabled Gulf coast refiners to supply gasoline to the east coast at 10 percent less than the delivered price quoted by California shippers and to increase gasoline shipments from the Gulf coast to the Atlantic seaboard from 141,193,000 barrels in 1935 to 153,026,000 in 1936. Similarly, kerosene shipments from California to the Atlantic coast declined from 1,189,000 barrels in 1935 to 1,133,000 in 1936 and intercoastal shipments of California gas oil and fuel oil from 877,000 barrels in 1935 to 625,000 in 1936.

Pipe-line developments.....		1090

A vigorous growth in demand characterized the natural-gas industry in 1936, and gas sales increased to an all-time high. The continued expansion in industrial activity and increases in the purchasing power of consumers were instrumental in causing an unusually large expansion in markets for natural gas in 1936. The industry absorbed virtually all of its excess pipe-line capacity, which had accumulated as the result of the construction boom in the late twenties, and embarked upon another period of expansion. The present emphasis, however, appears to be on enlarging the capacity of existing major lines through looping and extensions rather than on the construction of new systems.

Marketed production for the year reached an estimated total of 2,175,000,000 cubic feet, an increase of 13 percent over that in 1935. This marks the first time that the annual volume has exceeded 2,000,000,000 cubic feet. The value of the production at the wells was \$126,150,000, based upon the assumption that the average price was 5.8 cents per thousand cubic feet, as in 1935. (See fig. 75.) Imports from Canada were reported as 153,000,000 cubic feet and exports to that country as 85,000,000 cubic feet. Although final quantity data on exports to Mexico are not yet available, the total was about 7,400,000,000 cubic feet in 1936, compared with 6,727,000,000 cubic feet in 1935. Deducting the excess of exports over imports

¹ Data for 1936 are preliminary; detailed statistics with final revisions will be released later.

² Tables compiled by H. Backus, Petroleum Economics Division, U. S. Bureau of Mines.

from the total marketed production indicates that the consumption of natural gas in the United States in 1936 was 2,167,668,000,000 cubic feet. The total value of domestic sales at points of consumption in 1936 was about \$479,000,000, an average of 22.1 cents per thousand cubic feet. This represents a decline of 0.3 cent from the average value in 1935. The decline in value of natural gas probably reflects a slightly lower average price for domestic and commercial consumption and a relatively greater increase in sales of low-priced gas for industrial purposes.

⁶ Revised figure.

⁷ Exceeds 100 percent, as part of the natural gas treated for natural gasoline is blown to the air and not included in total consumption.

Of total domestic sales in 1936, 1,709,668,000,000 cubic feet was for industrial use; this was 15 percent more than the 1935 total of

1,496,216,000,000 cubic feet. Miscellaneous industrial demand, including petroleum refineries, increased approximately 13 percent, reflecting activity in the glass, ceramic, metal-working, and other industries. In some cities in the Middle West industrial demand increased more than 30 percent.

COMPETITIVE POSITION

The weighted average price of representative grades of fuel oil increased from 67 cents per barrel in 1933 to 92 cents per barrel in 1936. The average price of coal probably increased 33 percent from just before the code was inaugurated to the close of 1936. As the average

FIGURE 75.—Production and value of natural gas, 1918-36.

value of natural gas at points of consumption declined about 7 percent from 1933 to 1936, it may be assumed that the competitive position of natural gas among the primary fuels has strengthened in recent years.

In general, the consumer price of natural gas reflects principally the field price plus distribution costs. The trend in field prices in recent years has been downward, and in view of the size of developed reserves it appears unlikely that there will be a material increase in this price in the near future.

Indications are that the average distribution cost was reduced in 1936, as many pipe lines operated at a higher percentage of their capacity and as some of the larger systems improved their load factors by expanding their industrial markets. On the other hand, further expansion probably will involve increased capital expenditures and

rising costs for labor and materials, which will tend to prevent a run-away expansion in natural-gas sales at the expense of competing fuels.

In general, far greater confidence has been shown in the last few years as to the adequacy of natural-gas supplies, owing largely to a growing realization of the tremendous developed reserves in the Southwest now within reach of most of the principal cities. The problem of convincing prospective customers of the dependability of natural-gas supplies has always been a real one in the development of new markets. The virtual removal of this handicap in many districts facilitates to a marked degree the "selling" of natural-gas service to new communities. The foregoing does not mean that the factor of gas reserves is no longer vital, but it emphasizes the practical importance of an apparent psychological change in public opinion. The effect of this change is to render less potent the time-honored "dependability" defense of the vendors of competing fuels.

State taxes on natural-gas production have been actively discussed in recent months, particularly in the Southwest. The tax burden carried by natural gas in connection with both production and pipeline operations seems more likely to increase than decrease in the future.

EMPLOYMENT AND EXPENDITURES

Data on employment and expenditures at natural-gas wells were compiled by the Bureau of Mines in cooperation with the Census of Business for 1935. The accompanying table summarizes this information by States.

Employment and expenditures at natural-gas wells in 1935, by States

¹ In the field only—salaried employees at central administrative offices included with those employed on crude petroleum.

² Number of wage earners determined by averaging the total number reported on pay rolls the 15th of each month.

³ Includes cost of repair parts, machinery supplies, and all other materials and equipment necessary to maintain and operate the wells.

⁴ No purchases of electricity reported in partial coverage of the State.

Total wages and salaries for dry-gas production in the field in 1935 were \$11,181,000, or about 20 percent of the total value at wells. The average annual wage of about \$1,000, received by 7,288 wage earners, is probably somewhat lower than actual rates because at least 1,000 part-time workers are included in the employment figure. Many additional field workers were omitted entirely because their compensation for the year was so low as to indicate that they probably had other more remunerative sources of livelihood. Salaried field employees numbered 2,780 and were paid a total of \$3,901,000, an average annual salary of \$1,403. The Eastern States have a much higher pay-roll expense per thousand cubic feet of gas produced than do the Southwestern States because of the comparatively small productivity per well in the eastern fields.

Expenditures for supplies and materials at gas wells, exclusive of initial drilling costs and fuel, totaled \$7,495,000 in 1935. Total expense for fuel was \$2,288,000 and for electric current \$167,000.

GROSS PRODUCTION

Virtually all national and State totals of natural-gas production represent a summation of the quantities consumed for all purposes. Complete coverage of the quantity of natural gas reaching the surface by way of the 400,000 or more active oil and gas wells obviously is impossible, but for 1935 a particular effort was made to obtain a closer approach to gross-production totals than had been obtained previously. Estimates of gross production, which are given in the following table by States, represent essentially marketed production plus quantities used in repressuring, stored in the ground, or wasted. The figures on wastage are not complete, as no estimates were made of the quantities blown to the air at wellheads or of unmeasured losses in bringing in and operating wells and testing lines. In general, the figures shown cover residue gas blown to the air, shrinkage at natural-gasoline plants, and an estimate of transmission losses based on reports of "unaccounted-for" gas.

Repressuring.—Repressuring is the injection of gas, generally natural gas, into partly depleted oil and gas reservoirs primarily to increase oil recovery. An incidental but important aspect of repressuring in many fields is the conservation of large volumes of gas which would otherwise be wasted. The present firmness of petroleum prices is stimulating the growth of repressuring in many of the old oil fields.

In 1935 Oklahoma was the leading State in utilization of natural gas for repressuring; 39,055,000,000 cubic feet were returned to oil sands in the State for repressuring. In California 34,237,000,000 cubic feet were injected in 1935 for repressuring. Repressuring activities in nine other States brought the total volume of gas so used in the United States to 90,290,000,000 cubic feet, or nearly 4 percent of the gross production.

¹Marketed production plus quantities used in repressuring, stored in the ground, lost in handling, and blown to the air.

²Includes gas blown to the air at "stripper" plants, shrinkage at natural-gasoline plants, and transportation losses, but does not include wastage at wellheads.

Storage.—The storage of natural gas underground is closely allied to repressuring, as it also involves the return of gas to natural reservoirs. The purpose is to conserve surplus gas for future demand. At some operations dry-gas reservoirs are used, and at others partly depleted oil fields whose structural characteristics are suited to retention of the injected gas. The seasonal variation in demand for natural gas perhaps most frequently necessitates gas storage, particularly in regions where casinghead gas is used extensively for domestic and commercial purposes. Under such conditions, some of the residue casinghead gas produced during the summer months when natural-gas requirements are low is often stored for use in the cold season when consumer demands are heavy.

A total of 11,294,000,000 cubic feet of natural gas was stored in six States in 1935. The 5,760,000,000 cubic feet stored in Kansas and the 4,556,000,000 cubic feet in California represented over 90 percent of the quantity stored.

Waste.—Increasingly vigorous attempts have been made to reduce waste in natural-gas operations. The factors affecting waste in the transportation and distribution of natural gas are relatively simple and easy to classify and they exert a direct effect upon operating efficiency. Ordinarily an immediate financial advantage results from reducing gas waste within practical limits. This has been an effective stimulus to engineering research to improve methods and equipment for transporting, metering, regulating, and utilizing natural gas. Many technical improvements have made possible a considerable reduction in the percentage of gas leakage between the producing fields and the ultimate consumers.

Waste of gas from the standpoint of natural-gas production, however, is a far more intricate problem, as evidenced by the many recent attempts to reduce waste in the Panhandle. The nature of oil and gas production makes the loss of some gas into the atmosphere inevitable; for example, it is virtually impossible to bring in a gas well without some gas escaping. Growing interest in conservation and increasing opportunities to sell gas or put it to use in many fields have helped to improve operating technique to reduce gas waste. There is now a better understanding of the behavior and functions of natural gas in reservoirs, whether dry gas or oil and gas together. Realization that the gas has value in as well as above the ground at times has had a restraining influence upon uneconomic withdrawals.

The greatest losses in recent years and those that have been most difficult to bring under a reasonable degree of control have been the fault of operators whose financial interests seemed best served by producing large amounts of gas solely to extract the relatively small percentage of natural gasoline it contained. Proration and conservation regulations in States producing large quantities of flush oil have reduced the loss of casinghead gas considerably and continued improvement is anticipated. In the Panhandle field of Texas, which was credited with about 67 percent of all the losses in 1935, tremendous volumes of residue gas were still being blown to the air in 1936, although the average wastage in that year was far below that in 1934, the peak year.

MARKETED PRODUCTION

As already stated, the marketed production of natural gas in 1936 is estimated as 2,175,000,000,000 cubic feet, or nearly 260,000,000,000 cubic feet above the final figure (1,916,595,000,000 cubic feet) for 1935. The estimate for 1936 represents a new record, exceeding the previous high of 1930 by 12 percent.

Texas easily retained first rank among the producing States; in fact, its estimated production for 1936 (725,000,000,000 cubic feet) is more than double that of California, which ranked second.

The total value of the production at wells in 1936 is estimated as \$126,150,000 compared with \$110,402,000 in 1935. Figures on value by States have not been estimated for 1936, but the final figures for 1935 show that the average value at the wells ranged from 1.8 cents per thousand cubic feet in New Mexico to an average of 22.8 cents in New York. The average values at points of consumption for 1935 ranged from 9.7 cents per thousand cubic feet in Oklahoma to 71.3 cents in New York. The spread between the average value at the wells and the average value at points of consumption was largest in Washington, Illinois, and New York.

Natural gas produced in the United States and delivered to consumers, 1906-35, by States, in millions of cubic feet

WELLS

The increased demand for natural gas caused a material increase in field activity, and 2,070 gas wells were brought in during 1936 compared with 1,401 in 1935. Most of the completions in 1936 were in the Eastern States, but on the basis of potential or initial capacity completions in Texas probably outranked those in all the Eastern States combined.

In 1935 the number of producing gas wells declined from 54,130 on January 1 to 53,790 on December 31, indicating the abandonment of 1,741 wells. If the same rate of abandonment is assumed for 1936 the total number of wells producing at the beginning of 1937 is very close to that of December 31, 1934. Although the number of producing wells apparently is not increasing, the size of the shut-in reserves probably is growing larger as the large wells in the Midcontinent area replace the small wells of the Eastern States.

REVIEW OF FIELD DEVELOPMENTS BY STATES

Arkansas.—Production of natural gas in Arkansas in 1936 increased approximately 2,000,000,000 cubic feet or 30 percent over 1935, according to information furnished by George C. Branner, State geologist. Completion of J. D. Reynolds No. 1 in sec. 27, T. 15 S., R. 15 W. (Ouachita County), on the northeast flank of the old Smackover oil field, opened up new gas reserves in the Permian lime. Four additional wells producing varying amounts of natural gas and distillate were completed in the area before the end of the year. Two small gas wells were completed in the Smackover area of Union County.

In Nevada County, the Grove Land & Timber Co. No. 2 was completed late in the year with a reported initial capacity of 40,000,000 cubic feet of gas per day from the Nacatoch sand at 1,242 feet. The well is in sec. 10, T. 14 S., R. 20 W., a few miles southeast of Irma.

In western Arkansas three gas-well completions were reported as follows: One in the Roland-Dora field of Crawford County, one in the Vesta field of Franklin County, and one in Sebastian County. Nine gas wells were abandoned in Crawford County and two in Franklin County.

An active leasing campaign was carried on during the year in the southwestern counties of the State, based upon geophysical and sub-surface geological investigations. Increased exploratory drilling is expected in 1937.

California.—The most significant natural-gas development in California during 1936 was an increase of almost 17 percent in sales of gas to utilities, reflecting a continued expansion in demand for industrial and other purposes. The following comments are based on data taken from a report by Claude C. Brown, chief engineer, Railroad Commission, State of California.

Total production of natural gas increased approximately 15 percent—from 304,867,400,000 to 350,807,100,000 cubic feet, including 24,028,900,000 cubic feet blown to the air. Sales to utilities and others of 214,574,300,000 cubic feet represented 61.2 percent of gross production compared with 60.17 percent in 1935 and 59.6 percent in 1934. The utilities sold 57,000,000,000 cubic feet of natural gas to domestic consumers, 14,000,000,000 to commercial consumers, and 82,000,000,000 to industrial plants. Twenty-one billion cubic feet were used in generating electric power, 11,000,000,000 were utilized for company purposes, and 15,000,000,000 were sold to other than utility companies. Distribution losses were about 15,000,000,000 cubic feet. The total number of meters connected to gas pipe lines in California at the end of 1936 was 1,541,000, an increase of 61,000 over 1935.

¹ Figures compiled by Claude C. Brown, chief engineer, Railroad Commission, State of California.

The natural gas now being produced in California comes from 39 principal oil and gas fields of which 30 produce casinghead gas with oil and 9 dry gas only. Of the dry-gas fields, Buena Vista Hills, Buena Vista Lake, Buttonwillow, McDonald Island, Rio Vista, Semi Tropic, Tracy, and Trico are in the San Joaquin Valley area, and La Goleta is in the Coastal area. The dry-gas fields of the State are relatively unimportant, having produced only 5,000,000,000 cubic feet (1.4 percent of the total) in 1936.

The oil fields producing casinghead gas are distributed among the three productive districts of the State: San Joaquin Valley, Coastal, and Los Angeles Basin. The Kettleman-North Dome field was the source of 109,000,000,000 cubic feet of the 1936 production. Ventura with an output of 39,000,000,000 and Belridge with 36,000,000,000 were the next most productive areas.

The tremendous gas reserves at Kettleman Hills-North Dome are conveniently located about midway between the important markets of San Francisco and Los Angeles. There are 161 wells which range in depth from 7,000 to 8,000 feet and produce from five characteristically thick pay zones. Original bottom-hole pressures averaged about 2,800 pounds per square inch but have now been reduced to 1,250 pounds in some parts of the field. The productive area covers about 16,500 acres.

The first major field discovered in California through the use of geophysical methods of prospecting was opened up on June 2, 1936, by the K. C. L. Stevens No. A-1 well, 14 miles southwest of Bakersfield

in Kern County. It is known as the Ten Section field. The discovery well made 16,000,000 cubic feet of wet gas per day and 1,093 barrels of 61.5° A. P. I. gravity oil from 7,900 feet, with a gas pressure of 2,300 pounds on the casing and 1,950 pounds on the tubing. Other discoveries of the year included the Rio Vista dry-gas field, the Greeley field north of Ten Section, and the Tulare Lake Bed development. Deeper producing sands were proved at Torrance and other fields.

During the year 802 new wells were completed, of which 790 produced oil and gas and 12 dry gas only; 772 existing wells were deepened or redrilled and 449 abandoned.

From the best information available today, a reasonable estimate of the recoverable gas remaining in known reserves would approximate 25 trillion cubic feet. These reserves are thought to be sufficient to meet the estimated demand for 50 years.

No major gas lines were laid during 1936. The Tracy gas field, San Joaquin County, was provided with an outlet to a trunk line by construction of 10 miles of 8-inch line. Several of the newer gas fields will probably be connected to markets in the near future.

Colorado.—Natural-gas development continued to be very limited in Colorado during 1936; no new discoveries were made, and only one gas-well completion was reported. Data have been compiled by H. J. Duncan, supervisor, United States Geological Survey, Casper, Wyo.

The lone gas well resulted from a deepening operation in sec. 16, T. 3 N., R. 91 W., in the Thornburg field of Moffat County. A Dakota-sand gas well was drilled into the Nugget sand, where it had a flow of 2,500,000 cubic feet per day with a closed-in pressure of 900 pounds per square inch. A 22-mile, 3-inch line was laid from the Thornburg field to the town of Craig to augment the failing gas supply from the old Craig field.

Of the total 1936 marketed production in Colorado of 2,986,036,000 cubic feet, 2,791,195,000 came from the Hiawatha field (Colorado part) and was piped to Salt Lake City, Utah, and vicinity. The balance of the gas produced came from the Garcia (96,000,000), Berthoud (41,800,000), Craig (34,576,000), and Thornburg (22,465,000) fields. The Berthoud gas supplies towns in northern Colorado and Cheyenne, Wyo. Gas in the Garcia field is put through a gasoline plant and the residue used for fuel.

The following gas fields are shut in for lack of a market: Bell Rock and Powder Wash, Moffat County; Piceance Creek, Rangely, and White River, Rio Blanco County; and Garmesa, Garfield County.

It is estimated that 787,000,000 cubic feet of carbon dioxide gas was produced and wasted in the North and South McCallum fields of Jackson County. No commercial use has been found for this gas owing to its contamination by oil.

Illinois.—A. H. Bell, geologist and head of the Oil and Gas Division, Illinois State Geological Survey, has furnished the following data on natural-gas developments in Illinois.

No new gas fields were discovered in Illinois in 1936. Three gas wells were completed during the year, one in Bond County, one in Clark County, and one in Wabash County. The well in Bond County extended the producing area of the Ayers gas field to the west, adding an estimated 30 acres. The producing sand is the "Second Lindley" (the Bethel sandstone of the Chester series). Initial open-flow capac-

ity was estimated at 1,500,000 cubic feet per day. The Ayers gas field furnishes gas for municipal and industrial use in the town of Greenville.

The gas from the new wells in Clark and Wabash Counties is not being marketed and is being used only for power on the leases.

Indiana.—Although drilling for gas was somewhat less active in Indiana in 1936 than in 1935, enough new production was developed to check the decline in supply, according to a report furnished by M. M. Fidler, State gas supervisor, Indiana Conservation Department.

There were four outstanding scenes of activity in the gas fields of southwestern Indiana. Ten new gas wells were completed in the Oaktown field, Knox County, which brought the total number in this field to 38. During 1936 the Oaktown field became the largest source of natural gas in the State, furnishing more than 678,000,000 cubic feet and surpassing the output of the Alford field of Pike County. Production from the latter field continued to decline and amounted to approximately 400,000,000 cubic feet in 1936. Gas from these fields is consumed in cities of southwestern Indiana.

Six gas wells of small capacity were completed in the gas area in eastern Daviess County. A pipe line into the area is planned for the near future. In the Tell City field in Anderson Township, Perry County, five gas wells were completed, making a total of nine producing wells at the end of 1936 with a total open-flow capacity of approximately 20,000,000 cubic feet per day. Five gas wells were added to the gas field in Jefferson Township, Pike County, which was discovered in 1935. Drilling is expected to continue in 1937.

In all, 53 gas wells were completed in Indiana in 1936, of which 10 were of the wildcat variety. The demand for natural gas still exceeded the State production, and it is expected that active development will continue in Daviess, Pike, Gibson, and Perry Counties.

The old Trenton field of northeastern and east-central Indiana continued to furnish about 375,000,000 cubic feet of gas annually. Several wells of small daily potential were completed and were connected to pipe lines serving nearby towns. More than 700 wells are producing gas in the Trenton area, but many of these are used for private supply. If the Trenton wells are included, over 900 wells were producing natural gas in Indiana at the end of 1936. It is estimated that 90 percent of their product is used for domestic and commercial purposes.

Kansas.—Oil and gas development was extremely active and successful in Kansas in 1936. Statistical data on gas-well completions have been furnished by Kenneth K. Landes, assistant State geologist, Geological Survey of Kansas.

Eighty-eight gas wells were completed during the year, including 14 pool openers. Their total open-flow capacity exceeded 800,000,000 cubic feet per day. Among the gas wells are 24 wells which also produced oil. Completions in the older fields of eastern Kansas are not included because information concerning this area is lacking. The discoveries were as follows: Three each in Cowley and Haskell Counties, two in Finney, and one each in Barton, Elk, Grant, Pawnee, Pratt, and Rice Counties.

The Burrton-Stone field of Reno County was the most active area, with 18 completions listed. The wells ranged in capacity from 1 to 30 million cubic feet per day of gas. About half of the wells produced moderate amounts of oil in addition to gas. In the Hugoton field of

Stevens and Morton Counties, 17 wells were completed which ranged in capacity from 1.5 to 18 million cubic feet. The other gas field of outstanding importance in 1936 was Otis, in Reno County. Eleven gas wells were drilled, several of which exceeded 40,000,000 cubic feet per day in capacity. Two of these wells also produced oil. Production in the Otis field comes from the Reagan sand.

At the end of the year development was active in the central and western parts of the State, being stimulated by the increased demand.

Kentucky.—The natural-gas industry in Kentucky continued in 1936 to follow a course similar to that in 1935. The following information is taken from a report prepared for the American Institute of Mining and Metallurgical Engineers, by C. D. Hunter, geologist, Kentucky-West Virginia Gas Co.; I. B. Browning, geologist and operator, Ashland, Ky.; and N. W. Shiarella, geologist and operator, Owensboro, Ky.

Drilling was carried on at about the same, or a slightly increased, rate over that of 1935. In the important eastern Kentucky Devonian-shale gas area of Floyd, Martin, Pike, Knott, and Magoffin Counties more than 100 shale wells were drilled to maintain delivery capacity that would be adequate to meet pipe-line demands. The open-flow capacity of these wells averaged approximately 400,000 cubic feet per day each. The discovery and recent development of the large Oriskany-sand gas field in Kanawha County, W. Va., 100 miles to the northeast, have had no evident effect upon development of or demand for eastern Kentucky gas.

Seventy-two new gas wells with a total open-flow capacity of 70,000,000 cubic feet per day were completed in 1936 in the northwestern Kentucky fields of Ohio, Hancock, Daviess, McLean, Henderson, and Webster Counties. The producing sands range from Middle Mississippian to Middle Pennsylvanian in age. Most of the production comes from the Barlow, Jones, and Jett sands of the Chester series.

Considerable gas has been produced in connection with the development of the Bates Knot oil field, southwest of Livermore in McLean County. This structure is a faulted anticline and has proved a large producer of gas from both the Chester sands and the Pottsville sand. One well in the Jett sand (Tar Springs) had an open flow of 21,000,000 cubic feet per day at 1,220 feet. Three wells on this structure had flows of 13,000,000, 8,000,000, and 4,000,000 cubic feet, respectively, from the Pottsville sand at depths of 750 to 790 feet.

Increasing quantities of gas are being used in Kentucky for repressuring in the oil fields, particularly in the "Corniferous" lime and Weir sand pools of eastern Kentucky and to a smaller extent in western Kentucky.

Louisiana.—The natural-gas industry in Louisiana in 1936 was featured by an increase in drilling and production, particularly in the northern part of the State according to information supplied by Cyril K. Moresi, State geologist of Louisiana.

Gas-well completions increased almost 50 percent, or from 104 in 1935 to 155 in 1936. Intensive activity in the Monroe and Rodessa fields accounted for this gain and for 87 percent of the new gas wells in the entire State. The Monroe field continued to dominate the gas situation with 100 completed wells, followed by the Rodessa field with 35.

Marketed production of gas in Louisiana increased 17 percent over

1935 to 293,000,000,000 cubic feet. The accompanying table, which shows distribution of gas from the Monroe, Richland, and Epps fields of northeastern Louisiana, accounts for most of the gas produced.

*Distribution of gas produced from the Monroe, Richland, and Epps gas fields, 1935-36*¹

	1935 (M cubic feet)	1936 (M cubic feet)
Burned in carbon-black manufacture.....	54, 113, 611	45, 916, 169
Put into gas pipe lines.....	146, 928, 933	171, 679, 153
Utilized in the field.....	1, 051, 151	840, 636
Unaccounted for, losses, etc.....	1, 924, 795	1, 466, 017
Total production.....	204, 018, 490	219, 901, 975

¹ Data furnished by C. K. Moresi, State geologist, Louisiana.

In the Rodessa field, Caddo Parish, gas production put in lines increased about 20,000,000,000 cubic feet to 42,411,550,000 in 1936. The next most important gas area was the Sligo field in Bossier Parish, where output almost doubled to 8,756,643,000 cubic feet. In southern Louisiana there were important increases in gas production from the Bunkie field in Rapides Parish and the Bosco field in Acadia and St. Landry Parishes. The Iowa field in Calcasieu and Jefferson Davis Parishes continued to furnish about 4.5 billion cubic feet annually.

In the table on Monroe, Richland, and Epps production, it is interesting to note that the long-distance pipe lines continue to take greater proportions of gas at the expense of quantities disposed of in carbon-black production, field use, and various losses. Although the national demand for carbon black has been increasing rapidly, gas used for its production in Louisiana decreased about 14 percent, indicating a tendency to conserve the available gas in this district for markets where it commands a higher price.

Three new wet-gas fields were discovered in the northern part of the State during the year. The discovery well of the Sibley field, Webster Parish, was completed in June 1936 and had an initial capacity of 28,730,000 cubic feet per day from the Lower Glen Rose formation at 5,590 feet. Two more comparable wells were completed by the end of the year, but no pipe-line connection had been made. The Driscoll field, Bienville Parish, was discovered in April 1936. The initial production was 70,750,000 cubic feet, also from the Lower Glen Rose formation, at 6,141 feet. A third discovery from the same formation, now known as the Montcalm field, Lincoln Parish, was brought in from a depth of 6,576 feet and gaged 67,634,000 cubic feet per day. The two latter wells are producing into pipe lines. Gas was produced from deeper sands at Lake Bastineau, Bienville Parish, and Sligo, Bossier Parish.

Michigan.—Rapid growth of the natural-gas industry in Michigan continued in 1936. F. R. Frye, petroleum engineer, Michigan Department of Conservation, has furnished the following information on field developments.

Gas-well completions increased more than 100 percent over 1935 to a total of 206, 165 in old and 41 in new fields. Initial productive capacities were greater on the average than in previous years, being influenced by numerous completions in the Six Lakes field, where comparatively large wells are common. This gas field has become the

largest in the State; it extends more than 10 miles in length and has over 200 wells.

Two new gas fields were developed during the year; the Shaver field in Tps. 10 and 11 N., R. 4 W., Gratiot County, and the Ravenna field in T. 9 N., Rs. 14 and 15 W., Muskegon County. In the former, wells range in capacity from 1,000,000 to 25,000,000 cubic feet per day and in the latter from 300,000 to 3,000,000 cubic feet.

Gross gas production is estimated to have increased approximately 25 percent to 6,864,000,000 cubic feet, including about 1,850,000,000 casing-head and the balance dry gas. The Six Lakes, Austin, and Broomfield fields were the outstanding sources of dry gas. All produce from the Michigan "stray" sandstone, as do the other central Michigan dry-gas fields.

The most important natural-gas pipe-line development of the year was the construction and placing in service of 235 miles of 22-inch line to Detroit from a point near Zionsville, Ind. Deliveries were begun on July 9, 1936, and amounted to more than 3,800,000,000 cubic feet by the end of the year. The gas is piped from the Panhandle field of Texas.

The market for Michigan natural gas was expanded during the year by the inauguration of service to Lansing and Grand Rapids through new lines from the Six Lakes area.

Mississippi.—Information on natural-gas production and drilling in Mississippi during 1936 has been supplied by Henry N. Toler, State oil and gas supervisor.

The production of 13,004,835,000 cubic feet of natural gas established an all-time record for the State by a wide margin, being 2,619,706,000 cubic feet greater than the former peak in 1935. Virtually the entire output came from the Jackson field in Hinds and Rankin Counties. The only other production in Mississippi, that from the Amory field, Monroe County, declined to 36,264,000 cubic feet. A total of 5,275,962,000 cubic feet of gas from the Jackson field was piped outside the State to Alabama, Florida, and Louisiana.

Three producing gas wells and three dry holes were drilled in the Jackson field during the year. No drilling was done in the Amory field.

Ninety-nine gas wells were producing in the Jackson field and only one in the Amory field at the end of 1936.

Seven dry wildcats were completed in the coastal part of the State. In Wilkinson County a show of oil was found in the Cockfield formation below 3,800 feet in the Foster Creek Lumber Co. No. 1 well, sec. 8, T. 3 N., R. 1 E. In the same county, the Lanehart No. 1 well, sec. 22, T. 1 N., R. 2 W., had a showing of oil in the Miocene formation from 4,572 to 4,579 feet. The most significant wildcat development was the discovery in the Scanlon and Semmes No. 1 well, sec. 28, T. 4 N., R. 15 W., Lamar County, of the first salt dome that has been found in Mississippi. Salt was encountered below thick anhydrite at 2,522 feet.

Missouri.—According to the Biennial Report of 1937 of the Missouri State geologist, field activity in Missouri during 1936 continued on a routine basis, and completions numbered approximately 80, of which about 20 were gas wells and 40 dry holes. Almost two-thirds of all drilling was done in Jackson County. At the end of the year a pipe line was being built into T. 49 N., R. 32 W., to take gas from an extension of the old gas field in that area.

The largest well completed during 1936 had an initial capacity of 2,149,000 cubic feet from the Squirrel sand at 575 feet. It is in the Hammond gas field at Plattsburg, Clinton County.

Montana.—Drilling and production of natural gas in Montana increased moderately during 1936, according to a report prepared by H. J. Duncan, supervisor, United States Geological Survey, Casper, Wyo.

In old fields, 31 gas wells with a total open-flow capacity of 155,000,000 cubic feet were completed. A new gas discovery of some importance was made on the Price Dome or Duck Creek structure in Yellowstone County by completion of Metzger No. 1 with a capacity of about 10,000,000 cubic feet daily from a depth of 1,008 feet. It is shut in, as no market is available. Another discovery, probably of minor importance, was made on the Winifred structure, Fergus County, when a well in sec. 26, T. 22 N., R. 17 E., developed 200,000 cubic feet of gas from 392 to 505 feet. A second well was drilled to the sand before the end of the year.

The only pipe-line activity in 1936 comprised minor extensions to gathering lines and the construction of a small distribution system in the town of Cole, Phillips County. A booster station was added to the line from the Cedar Creek field to the Black Hills of South Dakota.

As indicated in the accompanying table total gas production in 1936 was 22,830,626,000 cubic feet, an increase of 16 percent over that of 1935. There were substantial increases in withdrawals from the three largest fields and smaller increases in the production from all other producing fields except Bowes. Industrial sales rose to an estimated total of 9,150,000,000 cubic feet, stimulated particularly by larger demands from the copper industry. Approximately 11,000,000,000 cubic feet were used for domestic and commercial purposes, 1,680,000,000 in field operations, and 1,000,000,000 in public-utility power plants.

¹ Data supplied by H. J. Duncan, supervisor, U. S. Geol. Survey, Casper, Wyo.

New Mexico.—The principal development in the natural-gas situation in New Mexico during 1936 was a marked increase in demand. Data on northwestern New Mexico have been compiled by H. J. Duncan, supervisor, United States Geological Survey, Casper, Wyo., and those on the southeastern part of the State by E. A. Hanson, United States Geological Survey, Roswell, N. Mex.

In southeastern New Mexico 13 gas wells with a total initial capacity of 272,000,000 cubic feet were completed, mostly incidental to the very active oil-development campaign in Lea County. There was little incentive to drill for gas because the available supply greatly exceeds prospective demand for the near future.

A total of 16,747,000,000 cubic feet of dry gas was sold in 1936, an estimated 21,000,000,000 cubic feet were processed for gasoline extraction, and about 2,000,000,000 were used in field operations.

The gas line that carries gas from southeast New Mexico into Arizona was extended from Casa Grande to Ajo, Ariz.

Activity continued to be very limited in the northwestern part of the State; only three gas wells were completed. These were all in the Kutz Canyon field and had an open-flow capacity of about 4,000,000 cubic feet.

Sales of gas from the northwestern fields, which increased about 16 percent over 1935, were as follows: Blanco 23,944,000 cubic feet, Kutz Canyon 1,191,660,000, and Ute Dome 451,848,000. Of the gas produced from Ute Dome, 149,299,000 cubic feet were piped to Durango, Colo. It is estimated that 50 percent of the gas produced was used for industrial and the remainder for domestic and commercial purposes.

Delivery of a liquid propane-butane mixture from the Rattlesnake field to the Indian agency at Shiprock was begun in April 1936 through a line laid several years ago.

Two additional carbon dioxide wells were completed on the Wilcox dome, Torrance County, and one in the Bueyeros field, Harding County. In the Bueyeros field four wells were drilling at the end of the year, and two dry-ice plants were under construction. A dry-ice plant with a rated capacity of 30 tons per day has been operating for some time on the Wilcox dome gas.

New York.—Exploration for natural gas in New York in 1936 outside of the proved fields was continued at about the same rate as in 1935. Although fewer wells were drilled, total initial capacity increased, according to information supplied by C. A. Hartnagel, assistant State geologist. Operations conducted in 9 counties in the central and western parts of the State resulted in 43 completions, of which 23 were producers having a total open-flow capacity of 293,000,000 cubic feet per day.

Development was greatest in the new State Line pool in the towns of Alma and Willing, Allegany County. Fourteen wells were drilled to the Oriskany sand at depths of 4,600 to 4,900 feet. Of these, 12 were productive, having an average capacity of 24,000,000 cubic feet and accounting for 97 percent of the new gas developed in the State during the year.

Six other Oriskany-sand test wells were drilled in Allegany County and four in Steuben County, none of which resulted in commercial production. Four wells were completed as producers from the White Medina sandstone at about 3,600 feet in the town of Leon, Cattaraugus County. They had initial capacities of 3,200,000; 2,500,000; 900,000; and 50,000 cubic feet per day.

Several shallow wells, which produce gas from the Trenton limestone near Camden, Oneida County, were connected to serve that town during the year. Through extension of a line that runs south-eastward from Binghamton, natural gas is now delivered to consumers in Rockland County, only 15 or 20 miles from New York City.

A 14-inch pipe line was laid from Potter County, Pa., to Rochester, a distance of 92 miles. Its chief customer will be a large industrial plant which has contracted for a maximum of 5,000,000,000 cubic feet annually.

Another pipe line which was completed during the year comprises 63 miles of 10-inch pipe and runs from Potter County, Pa., to a point near Arcade, Wyoming County, N. Y. From there one 8-inch line extends 43 miles westerly to Sheridan, Chautauqua County, and another 31 miles northerly to near East Lancaster, Erie County.

Ohio.—Drilling in Ohio increased approximately 10 percent during 1936, according to information in a report prepared by J. E. Schaefer, geologist, The East Ohio Gas Co., for the American Institute of Mining and Metallurgical Engineers. In the aggregate, 570 gas wells were completed.

The Clinton-sand area in central and eastern Ohio continued to be the most important source of gas and experienced the most active development, having 226 gas-well completions. A small pool was developed in Butler Township, Knox County, during 1936, in which 13 gas wells with an aggregate open-flow capacity of more than 15 million cubic feet a day were completed at a depth of about 3,000 feet. In lot 9 of Franklin Township, Tuscarawas County, a well was completed in the first Clinton sand at 4,354 feet. The initial open-flow capacity of the well after it was shot was 828,000 cubic feet and the closed pressure 1,325 pounds. A small gas well was completed in the red Clinton sand at 4,272 feet, in lot 4 of Wayne Township, Tuscarawas County. Clinton-sand completions accounted for 200,000,000 cubic feet, or more than two-thirds of the open-flow capacity developed in Ohio during 1936.

Twenty-nine small gas wells were drilled in the old Trenton lime field of northwestern Ohio. Six gas-well completions were recorded in the Newburg sand, which produces gas in Summit County and both oil and gas in Cuyahoga County.

Oriskany-sand development was unimportant in 1936. Two wells were added to the small Oriskany pool in Madison and Wayne Townships, Columbiana County, which had an initial capacity of 700,000 cubic feet each from about 4,450 feet and a closed pressure of 1,700 pounds. An Oriskany sand failure in sec. 13, Buffalo Township, Noble County, encountered dry sand at 4,128 to 4,145 feet, and one in sec. 9, Center Township, Morgan County, found salt water. Two efforts to extend production from a small Oriskany gas well in sec. 21, Sugar Creek Township, Stark County, resulted in dry holes through the Clinton sand.

In the Berea and shallower sands of eastern Ohio 279 gas wells were completed with a total capacity of 76,000,000 cubic feet per day. The Berea sand is the second most important productive formation in Ohio.

Twenty-one gas wells were completed in the Devonian shale and two in the Gordon sand during the year.

Oklahoma.—Developed gas reserves of Oklahoma were greatly increased in 1936. Information on field developments has been supplied by W. J. Armstrong, conservation officer, Oklahoma Corporation Commission.

During the year 126 gas wells were completed, a gain of 15 percent over 1935; of these, 11 were wildcat discoveries. Many oil wells in

the Oklahoma City field were plugged back to gas horizons in the Pennsylvanian and Simpson sands. The potential production of 130 gas wells in the field was 1,047,755,000 cubic feet of gas per day, as determined by the Bureau of Mines "back-pressure method." Much of this gas is used in gas-lift operations in the north part of the Oklahoma City field.

Oklahoma, with 18 gas-producing sands at various depths up to 6,500 feet, has one of the largest indicated gas reserves in the country. Perhaps the largest recently developed gas reserve is in the Fitts pool of Pontotoc County, where large volumes of gas occur in the Pennsylvanian above the oil-bearing horizons. The Cement field, Caddo County, which produces gas from five separate sands, is also an important reserve. Another large potential source of gas is in Texas County between the Hugoton field in Kansas and the Texas Panhandle field.

Records of the Oklahoma Tax Commission show that 111,607,000,-000 cubic feet of gas were produced and sold from dry-gas wells in 1936 and that 267,016,434,000 cubic feet of casinghead gas were processed for extraction of gasoline.

The gas-repressuring unit operation in the South Burbank oil pool, Osage County, continued with conspicuous success during the year, and a similar project was begun in the Keokuk Falls pool, Seminole County, in the summer of 1936.

Natural-gas pipe-line construction was limited to small additions to existing systems. Twenty-five miles of 8-inch line were laid from Red Oak to Poteau, Okla., and two lines about 10 miles in length were laid to the Cement pool from the Chickasha gas field.

Pennsylvania.—Drilling activity in Pennsylvania in 1936 increased somewhat over that in 1935. Data on the northwestern and middle parts of the State are taken from a report compiled for the American Institute of Mining and Metallurgical Engineers by J. G. Montgomery, Jr., superintendent and chief geologist, United Natural Gas Co.

Shallow-sand development was confined largely to productive areas, and no important new shallow-gas pools were discovered. The search for gas in the Oriskany formation continued at about the same rate as in other recent years. A well in Kinzua Township, Warren County, found gas in this horizon, but subsequently salt water appeared and at the end of the year the value of the discovery was still problematical. Another wildcat discovery struck 500,000 cubic feet of gas in the Oriskany formation in South Union Township, Fayette County. Although the gas was found last August, the well had not been completed at the end of 1936 because of drilling difficulties. A well in Butler County found salt water in the Oriskany. Other test wells were drilled in this formation in Fayette, Washington, Lawrence, Beaver, Crawford, Potter, and Tioga Counties.

Gas production from the shallower sands in 1936 does not appear to have changed greatly from that in 1935. The output of the Oriskany fields, however, increased almost 8,000,000,000 cubic feet to 37,700,000,000, owing to a large increase in output in the Ellisburg field, Potter County, and smaller increases in Sabinsville, Tioga County, and Harrison, Potter County, which more than offset declines in the Hebron, Potter County, and Farmington, Tioga County, fields. In the first 3 fields 23 new gas wells were brought in during the year.

New outlets for gas from the Oriskany formation were furnished by laying lines from the Hebron field to Clarion County, Pa., and from the Harrison field to northwestern New York State. A 14-inch line from the State Line field in Genesee Township, Potter County, Pa., to Rochester, N. Y., was placed in service in early 1937.

South Dakota.—The cities of Pierre and Fort Pierre continued to produce and consume the only natural gas produced commercially in South Dakota. E. P. Rothrock, State geologist, states that a show of gas was reported from a depth of 3,660 feet in a well at the Newell Experiment Farm.

Texas.—Gas-well completions in Texas numbered 388 in 1936, an increase of 110 over the preceding year. The largest gain was in the Panhandle field where there were 161 new gas wells, representing a 100-percent increase over 1935, in spite of a falling off in total drilling in that district. General drilling increased in all other Texas districts except the North Texas, where 166 (11 percent) fewer wells were drilled, and the East Texas field.

Gas production and disposition figures are taken from reports compiled by the Engineering Department, Railroad Commission of Texas.

The total dry-gas production of Texas in 1936 was reported as 575,275,066,000 cubic feet, of which 398,439,953,000 were "sweet" gas and 176,835,113,000 "sour" gas, which has a comparatively high hydrogen sulphide content. Production of 267,556,475,000 cubic feet of casinghead gas increased the total natural gas produced in the State to the tremendous quantity of 842,831,541,000 cubic feet. About 670,000,000 cubic feet of gas were processed for extraction of gasoline, and 216,000,000,000 cubic feet were burned in the manufacture of carbon black. The amount of residue gas blown to the air was greatly reduced.

A number of new gas areas were discovered during the year. The first production in Collingsworth County in the Panhandle district resulted from a well drilled on the Tinsley ranch, sec. 8, block 13, H. & G. N. survey. It produced about 2,000,000 cubic feet initial from 1,880 feet. In Hamilton County, North-Central Texas district, a "wildcat" on the L. T. Rhea farm, David Cook survey, was completed for 12,000,000 cubic feet from the Marble Falls limestone at 2,455 feet. A second well of similar size was drilled before the end of the year.

In south Texas drilling was very active, and several new gas fields were found. In southeastern McMullen County a gas well in sec. 86 on the Rhode ranch was completed in the Whitsett (upper Jackson) sand at a depth of 1,810 to 1,822 feet. Three more wells drilled in the area in 1936 proved about 1,000 acres for gas production. The Wood field in southern Starr County was opened in July by discovery of gas in the Frio sand at 963 to 975 feet. The Maetz gas area in Goliad County and the South Cole gas field were also discovered in 1936.

Gulf coast operations made large additions to known gas reserves, most of which, however, were associated with oil. In Harris County, northeast of the city limits of Houston, the Candelaria No. 1 blew out after 1 foot of sand was penetrated at 8,101 feet. After being brought under control, the well produced large volumes of gas with some high-grade oil. The shut-in pressure was 4,800 pounds, the highest ever recorded on the Gulf coast. The Lockridge gas field, Brazoria County, was opened by the Fairfield No. 1 well, which produced from 6,257 feet after being plugged back from 8,698 feet. Other gas discoveries

include Seabreeze, Chambers County, and three areas in Wharton County.

In eastern Texas the development of the Rodessa field was the outstanding feature of 1936. About 170 oil wells were drilled from which large quantities of gas were taken by pipe lines. Gas production in the Long Lake and Cayuga fields increased from about 3 billion to more than 10 billion cubic feet. A deeper gas horizon was found in the Cayuga field when a test well produced 12,000,000 feet of wet gas with distillate from the Trinity formation. New sources of gas from the Glen Rose formation were found in the Joaquin field, Shelby County, and 6 miles east of Carthage, Panola County. A 50,000,000-cubic foot well in the Woodbine sand was the discovery well of the Grapeland field in Houston County.

Demand for gas from the Panhandle field increased substantially in 1936 over 1935. The capacity of several major trunk lines leading north and east from the district was increased by laying new pipe and enlarging compressor installations. Improved conditions in the carbon-black and natural-gasoline industries stimulated construction of new plants in the field for manufacture of these products.

Several gas pipe lines were laid in 1936, and 122 miles of 10-inch pipe to serve industrial plants were under construction at the close of the year from the Tomball field to Houston, Port Arthur, and intermediate points. The capacity of the line will be about 60,000,000 cubic feet per day. In the Rio Grande Valley, lines were laid to connect McAllen with a Hidalgo Gas Co. line and to bring gas from the Mercedes and Mestanas fields, Hidalgo County, to Rio Grande Valley towns. A large system of lines was built in the Rodessa area to gather and market the new supplies of casinghead gas developed. Thirty miles of 6-inch line were laid from the Johnson pool, Foard County, to an electric power plant near Quanah, Hardeman County. Lines were built to furnish gas to the towns of Talco, Titus County, and Athens, Anderson County.

Utah.—There were no significant changes in the natural-gas industry in Utah during 1936, according to a report by E. W. Henderson, district engineer, U. S. Geological Survey, Salt Lake City, Utah. Only one gas well was completed; it was in the Clay Basin field, Daggett County, and had an open-flow capacity of 16,000,000 cubic feet and a closed pressure of 1,400 pounds per square inch from sands in the Dakota formation at 5,738 to 5,782 feet.

All wells in the Clay Basin field remained shut in during the year except for a short period when 44,842,000 cubic feet of gas were produced and used in the field for development purposes. The two producing wells in the Ashley Valley field, Uintah County, produced 51,476,280 cubic feet, all of which was used for domestic purposes. Two gas wells in the Cisco Dome field, Grand County, were abandoned, and the remaining eight wells continued to be shut in. The one gas well on the Last Chance structure, Emery County, did not produce during the year.

The inaccessibility of markets and the abundance of cheap, locally mined coal have discouraged development of natural-gas reserves in Utah.

Washington.—The natural-gas situation in Washington during 1936 remained much the same as in 1935, according to a report furnished by Harold E. Culver, supervisor of geology, Washington Department of Conservation.

Commercial production continued to be virtually limited to the output of the Rattlesnake Hills field, Benton County. The 15 active wells in this field supplied 183,177,000 cubic feet of gas to seven towns in the Yakima Valley, where it was used for domestic and industrial purposes. The compressor plant, which maintains a vacuum on the wells in the field, was enlarged during the year as a means of stimulating production. Work was resumed on a deep test well in the hope of discovering a new source of gas in the sediments which are thought to underlie the basalt flows which now supply gas.

Progress was reported on test wells in Chelan, Grant, Grays Harbor, Jefferson, King, Snohomish, and Yakima Counties and in the area north of Bellingham, Whatcom County, where small quantities of gas are put to domestic use; however, no new discoveries were made.

The production of carbon dioxide gas from the springs and shallow wells near Klickitat, in southern Washington, was increased in 1936 by drilling several new wells. The capacity of the dry-ice plant which utilizes this gas was increased from 3 to 5 tons per day, and 1,085,551 pounds of the product were sold during the year.

West Virginia.—There was a marked increase in natural-gas activity in West Virginia during 1936 in response to the pressure of larger market demand. The following information is taken from a report compiled by David B. Reger, consulting geologist, Morgantown, W. Va.

Although no new fields were discovered, large extensions of proved territory were developed, particularly in the Oriskany-sand area of Kanawha County. Forty-five Oriskany-sand gas wells were completed with a total initial capacity in excess of 200,000,000 cubic feet per day. Their open-flow capacity ranged from 100,000 to 15,000,000 cubic feet and their closed pressure from 1,200 to 1,900 pounds. The productive area, of which approximately 11,000 acres are regarded as proved, extends about 18 miles north and south and 6 miles in maximum width in the Elk, Loudon, Malden, and Poca districts. The Middle Devonian brown shale has been found productive of gas in wider areas of Boone, Lincoln, Putnam, and Kanawha Counties.

The number of gas wells completed increased only moderately in 1936 (to 461 from 417 in 1935), but the open-flow capacity of the new wells more than doubled (to 554,119,000 cubic feet). It is estimated that at the close of the year about 100 more wells were drilling than at the close of the previous year.

From the gas standpoint, Cabell and Kanawha Counties were outstandingly active, contributing over 60 percent of the newly developed capacity. The next most active counties were Roane, Ritchie, Calhoun, Logan, and Boone.

In addition to routine extensions to gas gathering systems, one major line was constructed in 1936. It consists of 95 miles of 12½-inch pipe extending from a compressor station near Clendenin, Kanawha County, northward to Hastings, Wetzel County. A 15-mile feeder line of the same size was built to join the main line at Burnt House, Ritchie County. The gas is carried into Ohio and Pennsylvania. The rated capacity of the line is about 40,000,000 cubic feet per day at 300 pounds. The pipe is of seamless steel, and all joints are electrically welded. A calcium chloride brine dehydrator to free the gas of moisture was installed at the compressor-station end of the line.

Wyoming.—Only four gas wells were drilled in Wyoming during 1936, but two of these resulted in the discovery of new gas reserves, as described in the following abstract of a report compiled by H. J. Duncan, supervisor, United States Geological Survey, Casper, Wyo.

The Hintze No. 1 well in sec. 18, T. 22 N., R. 78 W., on the East Allen Lake structure in Carbon County developed approximately 11,000,000 cubic feet of gas per day from the Sundance sand at 2,044 to 2,084 feet. The discovery had not been completed at the end of the year because the owners of the well planned to deepen it to search for oil production. It is located within a few miles of the Allen Lake-Laramie gas line.

The other discovery was made in the Shawnee area, Converse County, when the Salisbury No. 1 well in sec. 27, T. 32 N., R. 69 W., produced approximately 7,000,000 cubic feet of gas initially at a total depth of 580 feet. At present there is no other market for the gas except for fuel in drilling operations.

An additional supply of gas was produced with oil from the basal Sundance sand in the Lance Creek field, Niobrara County.

It is estimated that 34,581,000,000 cubic feet of gas were produced in Wyoming in 1936, of which about 10,560,000,000 were casinghead and the remainder was dry gas. The Salt Creek field was by far the largest source, with a production of 10,155,890,000 cubic feet of casinghead gas (about the same as in 1935). This gas was put through gasoline plants and disposed of as follows: 7,029,526,000 cubic feet were returned to the oil sands for gas-drive purposes, 1,368,351,000 were used in field operations and in generation of electricity, 824,670,000 were consumed by gasoline plants and compressor stations, and 385,767,000 were used for domestic and commercial purposes. Production in 1936 of 1 billion to 3½ billion cubic feet of gas each was reported for the South Baxter Basin, Big Sand Draw, Lance Creek, Wertz, North Baxter Basin, Elk Basin, Little Buffalo Basin, and Mahoney fields, which are named in order of their importance.

It is roughly estimated that 14 billion cubic feet of gas produced in Wyoming were used for industrial and commercial purposes, 7½ billion for domestic purposes, 2½ billion for field operations, and 2½ billion for the manufacture of carbon black.

Very little gas was wasted in the State except that from the Stock Oil Co. Allen No. 1 well in lot 52, T. 56 N., R. 97 W., Garland field, Big Horn County, which blew out of control on January 19, 1936, and remained out of control through December 1936. It is estimated that 16,000,000,000 cubic feet of gas were dissipated from this operation.

No trunk pipe lines were constructed during 1936. A new gasoline plant capable of processing 5,000,000 cubic feet of gas per day was erected in the Lance Creek field. About 1.7 gallons of gasoline are obtained per thousand cubic feet and the residue is used for field operations and in the carbon-black plant, which consumed an estimated 2,500,000,000 cubic feet during 1936. There is no other market for gas from this field.

CONSUMPTION

The consumption of natural gas in the United States is less than 1 percent under the marketed production, as the excess of exports over imports is relatively small and stocks are negligible. The largest item in the consumption of natural gas is that representing field use;

this accounts for about 30 percent of the total. The next most important uses are "Other industrial" and domestic, which comprise about 25 and 15 percent, respectively. Natural gas consumed for domestic purposes has the highest value; the average for 1936 was estimated as 72.8 cents per thousand cubic feet. The lowest values are in field use; this average for 1936 was about 5 cents per thousand cubic feet.

Data on the number of consumers of natural gas in 1936 were not obtained, but the over-all totals may be estimated as 7,500,000 domestic, 650,000 commercial, and 40,000 industrial consumers. These totals include about 2,500,000 domestic and commercial consumers who used mixed gas containing various proportions of natural gas.

Natural gas consumed in the United States, 1925-35

¹ Included under "Other States."

² 1931: Utah includes Alaska, Arizona, and Washington; 1932: Utah includes Alaska and Washington.

³ Service inaugurated in 1931, hence figures represent operations for only part of year.

⁴ North Dakota includes Minnesota.

⁵ Includes natural gas piped from Canada.

Treated for natural gasoline.—Until 1935 the trend in the average yield of natural gasoline per thousand cubic feet of gas processed was downward, owing to the treatment of increasingly large volumes of lean natural gas in the Texas Panhandle field and to progressively greater stabilization. However, the average yield increased in 1935 and 1936 because of the curtailing of operations at the "stripper" plants in the Panhandle and the rapid growth in natural-gasoline production in the east Texas field, a high-yield area, and in 1936 because of the growth in importance of production at Rodessa, where the casinghead gas is also relatively rich.

Natural gas treated at natural-gasoline plants in the United States, 1926-35, by States

¹ Exceeds 100 percent, as part of the natural gas treated for natural gasoline is blown to the air and not included in total consumption.

² Less than 500,000 cubic feet.

These events apparently account for the reversal in the trend of gasoline recovery. The low average of 0.86 gallon per thousand cubic feet in 1934 was increased to 0.91 gallon in 1935, and probably a moderate increase carried over into 1936. It is estimated that 1,900,000,000,000 cubic feet of natural gas were treated for the extraction of gasoline in 1936, an increase of about 80,000,000,000 cubic feet over 1935. The total so treated was about 88 percent of the total consumption of natural gas in the United States in 1936, compared with 95 percent in 1935 and 101 percent in 1934. This decline in ratio results primarily from the progressive reduction in the wastage of residue gas.

The accompanying table on natural gas treated at natural-gasoline plants by States indicates the conspicuous growth of the natural-gasoline industry in Texas during the past 10 years. The quantity of gas processed in California in 1929, 1930, and 1931 increased substantially, but aside from this period such operations in California and Oklahoma have remained relatively stable. Among less important States in the industry, West Virginia and Louisiana have treated gradually less gas, and Kansas has treated more, particularly since 1932. Quantities of gas treated in the United States have increased annually since the low point of the depression in 1932 but are still less than in 1929-31.

Domestic and commercial.—The volume of gas used for domestic purposes increased about 10 percent in 1936 to an estimated total of 345,000,000,000 cubic feet, compared with 313,498,000,000 cubic feet in 1935. Its value at points of consumption increased about 7 percent to \$251,000,000. An increase in the quantity of gas consumed by the average domestic customer probably reduced somewhat the average unit price received by gas companies, as most price schedules offer advantageous rates on gas used in excess of a prescribed minimum. Commercial demand is estimated to have expanded almost 13 percent over 1935—to 113,000,000,000 cubic feet having a value of about \$55,000,000. Sales of gas to domestic and commercial users combined accounted for 64 percent of the total revenue from natural gas in 1936 but represented only 21 percent of the total volume consumed.

Domestic and commercial consumption of natural gas in the United States in 1935, by States ¹

¹ Includes natural gas used with manufactured gas.² Maryland Includes District of Columbia and Virginia.³ Utah includes North Dakota and Washington.

Field.—Natural gas used in field operations, which include the generation of power for drilling, reconditioning, and pumping wells and other purposes, is thought to have increased about 10 percent over 1935 to 640,000,000,000 cubic feet in 1936. Natural gas used in the drilling of wells for oil and gas, a major field use, increased 19 percent in 1936, and other field uses showed similar gains. Power equipment used in oil fields for compressing gas and for pumping oil and water probably has been utilizing progressively larger amounts of natural gas in recent years.

Carbon black.—The consumption of natural gas by the carbon-black industry reached new high levels in 1936 in response to a record-breaking demand. The total quantity of gas burned at carbon-black plants in 1936 was 283,421,000,000 cubic feet—17 percent more than in 1935 and almost 17,000,000,000 cubic feet more than in 1930, the previous record year.

Petroleum refineries.—From 1927 to 1933 the use of natural gas as a refinery fuel declined steadily, as many companies found it economical to use their own still gases as fuel rather than to purchase natural gas. In 1934 and 1935, however, the trend was the other way with the growing realization that still gases, or some fractions of them, were more valuable as processing material in motor-fuel manufacture. In 1935 natural gas burned as fuel at petroleum refineries totaled 80,175,000,000 cubic feet; probably the total in 1936 was somewhat larger, as crude runs to stills increased materially in 1936 over 1935 and prices of competing fuels were generally higher.

Electric public-utility power plants.—Public-utility power plants increased their use of natural gas as fuel in generating power to 156,080,000,000 cubic feet in 1936, the largest consumption in recent years and almost 25 percent higher than in 1935. This pronounced increase, which was proportionately greater than the rise in electric-power generation in the country, indicates a growing preference for natural gas instead of fuel oil and coal.

Portland-cement plants.—The portland-cement industry, which has shared in the recent expansion in industrial activity, consumed an estimated total of 36,923,000,000 cubic feet of natural gas in 1936, a gain of 38 percent over 1935 but less than the record levels of 1929 and 1930.

Other industrial.—The trend in sales of natural gas for industrial purposes, other than those mentioned, is important chiefly as it throws light on the competitive fuel situation in the manufacturing industries and the degree to which the interstate systems have augmented their domestic and commercial business with off-peak industrial loads. Indications are that sales of natural gas for miscellaneous industrial purposes increased about 16 percent in 1936 over 1935. As this gain exceeded the percentage increase in total consumption and probably was greater than the increase in total B. t. u. consumption of the enterprises using natural gas, it may be assumed that natural gas maintained its competitive position as an industrial fuel. Moreover, this business probably was more profitable in 1936 than for several years, as the volume of sales for preferential uses has grown to a point where the temptation to sell wholly on a volume basis has been virtually removed.

Industrial consumption of natural gas in the United States in 1935, by States and uses

² Maryland includes District of Columbia and Virginia.

³ Utah includes North Dakota.

⁴ Gas used in manufacture of carbon black included under "Miscellaneous" for United States total and under "Other industrial" for State total to avoid disclosing figures of individual operators.

Mixed gas.—Information on the blending of natural gas with manufactured gas in the production of mixed gas is not available for 1936, but there is little doubt that expansion in this branch of the industry was proportionate with the rise in total distribution. In fact, in 1935 the use of natural gas to enrich manufactured gas was increasing faster than total consumption. In 1935, 54,000,000,000 cubic feet of natural gas were mixed with manufactured gas, compared with 48,970,000,000 cubic feet in 1934. The average value of this natural gas at points of consumption (assumed to be the same as the average value of the mixed gas) was 92.1 cents per thousand cubic feet, compared with a national average of 22.4 cents per thousand and with a weighted average of 46.5 cents for the States distributing mixed gas.

INTERSTATE MOVEMENTS

Data on interstate movements of natural gas in 1936 are not available, but the final figure for 1935 (469,024,000,000 cubic feet) was 13 percent higher than that for 1934. For many years the trend has been toward interstate shipment of increasing proportions of the total gas requirements of the country as a corollary to the growth of long-distance gas transmission. The total gas shipped interstate in 1935, for example, was equivalent to 24.6 percent of the total consumption, compared with 23.5 percent in 1934.

Texas and Louisiana were the source of 54 percent of all gas entering interstate commerce in 1935, followed by West Virginia, which contributed 15 percent. Fourteen other States exported smaller amounts of gas. Interstate shipments increased from all States except Illinois, where they declined slightly, and Ohio, where the total movement to other States declined 21 percent from 1934. Interstate movements increased most in 1935 over 1934 between Texas and Illinois and West Virginia and Ohio. The largest single movement in 1935 was that from West Virginia to Ohio.

There is reason to believe that the interstate volume has continued to expand through 1936 and early 1937, with perhaps some acceleration.

Pipe-line developments.—Most of the important natural-gas pipe lines constructed in 1936 were built east of the Mississippi River. The large Detroit gas market was supplied with natural gas by completion of a connecting link to the Panhandle Eastern line; this comprised 235 miles of 22-inch pipe from a point near Zionsville, Ind., to Detroit, laid at a cost of \$5,400,000. The gas is brought from the Texas Panhandle and Southwestern Kansas fields. Other construction work in Michigan included 46 miles of 10-inch pipe to Grand Rapids from the Six Lakes field in the central part of the State and 62 miles of 20-inch line from the same field to Lansing.

About 140 miles of 10- and 8-inch pipe line were built to bring Oriskany-sand gas from the fields of Potter County, Pa., to Batavia and Dunkirk, N. Y. In January 1937 deliveries commenced through a new 14-inch line from the same area to Rochester to supply the Eastman Kodak plant and other consumers near the line. A 12¾-inch line was built from Hebron Township, Potter County, Pa., southwestward 113 miles to Pew Station, near New Bethlehem, Clarion County, Pa., where it connects with two trunk lines running into the Pittsburgh district. One major gas line was laid in West Virginia during the year; it runs from Clendenin, Kanawha County, northward to Hastings, Wetzel County, where it connects with lines into Pennsylvania and Ohio and comprises about 100 miles of 12¾-inch pipe. Most of the new construction in the Appalachian fields in 1936 was based largely upon the recent development of substantial gas reserves in several Oriskany-sand areas at depths of 4,000 to 5,000 feet.

In the midcontinent and southwestern part of the country there were numerous small gas pipe-line projects but very few large ones. In Kansas a 20-inch line was laid from the Hugoton field eastward, a distance of 107 miles, to connect at Mullinville with a 26-inch trunk line taking gas from the Texas Panhandle to Nebraska and other northern areas. From the Otis field, Rush County, Kans., 125 miles of 6- and 8-inch lines were laid to Holdredge, Nebr. A line to supply gas to industrial consumers was being completed at the end of 1936 in the Texas gulf coast; it runs from the Tomball field, Harris County, 120 miles to Houston, Baytown, Port Arthur, Beaumont, and Port Neches. The line is of 10-inch pipe and has a rated capacity of 60,000,000 cubic feet per day.

For the natural-gasoline industry the year 1936, like 1935, was one of general tranquillity and progress. Production increased 7 percent over 1935, and demand was 5 percent higher. Stocks increased but

FIGURE 76.—Number and capacity of natural-gasoline plants on January 1, 1928, 1930, 1932, 1934, and 1936.

not enough to cause pronounced weakening in the market. A decline in exports was nearly balanced by a gain in "direct" shipments, although refinery demand continued to account for more than 80 percent of the total.

The average plant value of natural gasoline for 1936 is estimated at 4.6 cents per gallon, an increase of 0.3 cent over 1935. Although this gain undoubtedly permitted some of the less-profitable plants to keep going, it is doubtful if it was enough to prevent a further decline in the total number operating. (See fig. 76.)

¹ Data for 1936 are preliminary; detailed statistics with final revisions will be released later.

FIGURE 77.—Trends in average value of natural gasoline, spot price of gasoline, and stocks of natural gasoline, 1918-36.

PRICES AND MARKET CONDITIONS

Prices of natural gasoline in 1936 were probably satisfactory to most producers; at least fewer charges of dumping and distress sales were made than for several years.

The average value of natural gasoline at the plants in 1935 was 4.3 cents per gallon compared with 3.9 cents in 1934. The final figure for 1936 is not available, but the trend of spot prices indicates that the plant value was about 4.6 cents per gallon.

The records of spot prices of a representative grade of natural gasoline for recent years indicate an increasing tendency for quotations to resist the spring slump. In other words, prices in the last 2 years have not fluctuated as much as those in prior years. (See fig. 77.)

Spot price of Oklahoma natural gasoline, grade 26-70, on specified dates in 1936, with monthly and yearly averages, in cents per gallon

EMPLOYMENT AND EXPENDITURES

Under a cooperative arrangement with the Bureau of the Census, the Bureau of Mines collected data on employment, wages, salaries, and expenditures for the natural-gasoline industry in 1935. This census of the industry was the first ever made which did not include petroleum production. The results were published in a release of the Census of Business dated March 3, 1937, and the State totals are summarized in the following table.

In 1935 the average number of wage earners employed at natural-gasoline plants was 7,997; salaried employees, including salaried officers, supervisory and technical employees, and the clerical force at the plants, totaled 1,052 about the middle of December. In addition, there were a thousand or more salaried employees at central administrative offices devoting at least half their time to natural-gasoline operations.

Wages totaled \$10,567,000 and plant salaries \$2,105,000. The "average wage" was, accordingly, about \$25 per week and the "average annual salary" about \$2,000. Wages and salaries at the plants were 18 percent of the plant value and total expenditures for supplies and materials, fuel, and electricity were also 18 percent.

The principal expense, the cost of the gas, was not included in the expenditures reported.

Employment and expenditures at natural-gasoline plants in 1935, by States

¹ Number of wage earners determined by averaging the total number reported on pay rolls the 15th of each month.

² Includes salaried officers, supervisory and technical employees, and clerks and others receiving compensation on a salary basis.

³ Includes cost of repair parts, machinery supplies, additional units, new gathering lines, and all other equipment necessary to maintain and operate the plant, but excludes costs of new plants.

PRODUCTION

Trends in total output.—As shown in figure 78, there is a close relationship between crude-oil production and natural-gasoline production. Both declined sharply during the depression. Since then they have recovered materially, particularly crude-oil production, which reached a new record in 1936.

As 1936 opened, the daily average production of natural gasoline was about 5,000,000 gallons, but declines in the spring months brought the average down to about 4,500,000 gallons by the middle of the year. Substantial gains in output in the Panhandle, Kettleman Hills, and Rodessa fields in the fall and early winter raised the average to about 5,400,000 gallons in December.

¹ Preliminary.

California.—Production in California in 1936 totaled 587,829,000 gallons, or 10 percent above the 1935 output. Although this marked the third successive yearly gain in production in the State, the 1936 total was far under the peak (840,325,000 gallons) of 1929. Despite a slump in output in the spring months following reductions in crude-oil production, Kettleman Hills established a new record output of 171,600,000 gallons, or nearly 18,000,000 gallons above the 1935 total. The rest of the increase in production in the State in 1936 over 1935 was registered in the smaller fields; the old substantial producers, Long Beach, Santa Fe Springs, Ventura Avenue, and Huntington Beach, showed little change.

² Preliminary figures.

Texas.—Despite a material gain in crude-oil production the output of natural gasoline in Texas declined in 1936. This unusual occurrence resulted primarily from curtailed operations at the “stripper” plants utilizing “dry” gas in the Panhandle; in fact, the production from “wet” or casinghead gas increased materially.

Production in the Panhandle in 1936 was 208,326,000 gallons compared with 276,602,000 gallons in 1935. Most, or perhaps all, of the decrease was recorded at the “stripper” plants. Although at various times “stripping” has apparently been outlawed in Texas, most of the “stripper” producers have continued operations on a scale contingent upon injunctions and the ability to find markets for the residue gas.

Production in the east Texas field again recorded a material gain; the output increased to 135,573,000 gallons in 1936, or 73 percent more than in 1935. This gain reflected chiefly increased operations due to the construction of new units and the expansion of gas-collecting facilities at existing plants.

Natural gasoline produced and natural gas treated in the United States in 1935, by States

State	Number of operators ¹	Number of plants operating	Natural gasoline produced			Natural gas treated

¹ A producer operating in more than 1 State is counted only once.

Oklahoma.—Oklahoma, like California, has increased its output of natural gasoline in recent years, but production is still far below that of 1929 and 1930. In 1936 the output was 418,721,000 gallons compared with 379,913,000 gallons in 1935 and 676,030,000 gallons in the peak year 1929. The gain in output in 1936 was distributed among the major producing districts, indicating that it was related to the increase in crude-oil production rather than to new discoveries or construction.

Louisiana.—Production in Louisiana in 1936 was 67,503,000 gallons, or 36 percent above the total in 1935. This gain, which brought production virtually to the record level of 1930, resulted primarily from the treating of gas from the Rodessa oil field.

Other States.—The output in West Virginia continued to recover from the depression slump in the demand for gas; the total for 1936 was 46,288,000 gallons compared with 42,433,000 gallons in 1935. Both Kansas and New Mexico showed substantial gains in production in 1936; the increase in Kansas was due chiefly to increased casinghead-gas production and that in New Mexico to new construction.

CONSUMPTION AND MOVEMENTS

The indicated domestic consumption of natural gasoline in 1936 was 1,750,728,000 gallons, of which 84,126,000 gallons were "losses." Of the remainder, 85 percent was utilized at refineries, 7 percent was exported, and 8 percent went into "direct" shipments to bulk plants, jobbers, and retailers. Compared with similar data for 1935, these ratios indicate a small gain in the relative importance of refinery and "direct" uses which offset a decline in exports.

¹ Includes quantities run through pipe lines east of California.² As reported to the Bureau of Mines by manufacturers.

* Preliminary.

Refinery utilization.—The percentage of natural gasoline blended in refinery gasoline in 1936 was 6.70 compared with 6.68 in 1935. Except in 1933, the ratio has remained remarkably near 6.70 percent for the past 5 years.

The most important change in blending operations in 1936 occurred at refineries in the Texas Gulf Coast district, where 170,352,000 gallons were utilized in 1936 compared with 110,838,000 gallons in 1935. The Indiana-Illinois-Kentucky district also made a material gain in natural-gasoline consumption. Although most of the other districts used more natural gasoline in 1936 than in 1935, the percentages of the total refinery gasoline so used were lower because the percentage gain in total output of gasoline exceeded the relative increase in blending.

¹ Preliminary.² Includes natural gasoline run through pipe lines.

"Direct" sales.—Data on "direct" sales, that is, domestic movement to consumers other than refineries, are important as they reflect the extent to which the manufacturers depend upon refinery sales and indicate the use of stabilized natural gasoline as a fuel without blending. Such sales increased in quantity from 116,340,000 gallons in 1935 to 139,230,000 gallons in 1936 and in percentage of total domestic sales, from 8 to 9 percent. The gain would probably have been even larger if prices paid by the refiners had not stiffened.

"Direct" sales are made to virtually every State, but most of the gasoline so sold moves northward from Texas and Oklahoma. Texas continued to be the largest "direct" shipper but was closely pressed by Oklahoma. The largest interstate movement of this type in 1936 was that from Oklahoma to Illinois.

Pipe-line shipments.—The movement of natural gasoline by pipe line in California increased from 31,290,000 gallons in 1935 to 52,500,000 in 1936. Comparable data are lacking for the rest of the country in 1936, but the total quantity moved is believed to have increased.

Shipments of natural gasoline to jobbers, retailers, and refinery-owned bulk plants in 1936,¹ by States

¹ Preliminary.

Water-borne shipments.—According to data reported to the Bureau of Mines by manufacturers, exports of natural gasoline totaled 107,058,000 gallons in 1936 compared with 135,366,000 gallons in 1935. The Bureau of Foreign and Domestic Commerce reports natural-gasoline exports for 1936 as 1,807,000 barrels (75,894,000 gallons); the disparity of about 30,000,000 gallons between the two figures was probably due to differences in classifying exports of gasoline and natural gasoline.

The only other important water-borne movement of natural gasoline is that from the Texas Gulf to the East coast. Complete data on this movement are not available, but refinery deliveries to the East coast, most of which came from the Gulf by tanker, were reported as only 37,918,000 gallons in 1936 compared with 61,109,000 gallons in 1935.

Exports of natural gasoline to Canada, most of which probably moved in tank cars, totaled about 29,000,000 gallons in 1936 compared with about 20,000,000 gallons in 1935.

STOCKS

In 1935 stocks of natural gasoline declined about 22,000,000 gallons—from 177,086,000 gallons at the beginning of the year to 155,316,000 gallons at the close. In 1936 the trend was reversed, and stocks increased about 15,000,000 gallons to a total of 170,310,000 gallons on December 31, 1936. As the improvement in prices in 1935 was held to be related to the decline in stocks during the year, it seems unusual that prices continued to improve in 1936 with rising stocks. However, most of the net increase in stocks in 1936 was registered late in the year in California; stocks in the Midcontinent district, where most price movements originate, were probably consistently lower in 1936 than in 1935.

¹ Preliminary.¹ As of Feb. 29.

TECHNICAL DEVELOPMENTS

Yields.—No startling technical developments were made in natural-gasoline manufacture in 1935 or 1936. The average yield, which increased from 0.86 gallon per thousand cubic feet in 1934 to 0.91 gallon in 1935, probably increased still further in 1936. These gains may reflect the addition of improved equipment and the elimination of many small inefficient plants, but probably they reflect chiefly the rise in importance of East Texas, a high-yield area, and the decline in importance of the Panhandle, a low-yield area.

Production by processes.—Although absorption continued to be the principal means of producing gasoline the compression process made a notable come-back in 1935, when the total output at plants using that process rose to 180,953,000 gallons from 148,150,000 gallons in 1934. Similar data are not available for 1936, but undoubtedly compression production increased further as the output in East Texas, where the process is popular, increased materially.

Even the charcoal process, production from which had been declining since 1929 and which appeared due for early extinction, held its own in 1935.

¹ Includes combination of absorption process with compression and charcoal processes.

Trends in vapor pressures.—The average vapor pressure of production in 1936 was about 20.25 pounds (Reid), or 0.25 pound higher than in 1935. This gain probably was related to the increase in yield, as yields and vapor pressures generally vary directly. The usual seasonal trend in vapor pressures was evidenced in 1936; the high (21.5) was in January and February and the low (18.6) in July. The average vapor pressure of refinery shipments rose from 20.5 pounds in 1935 to 20.9 pounds in 1936, but the average for "direct" shipments declined from 16.1 to 15.9 pounds and that for exports from 18.7 to 17.4 pounds.

Polymerization.—In Minerals Yearbook, 1936, the development of polymerization as a process to convert natural gas into high-octane gasoline was mentioned. Undoubtedly some progress was made along these lines in 1936, although in the natural-gasoline industry the work was probably mainly research.

LIQUEFIED PETROLEUM GASES

Domestic sales of liquefied petroleum gases continued to increase rapidly and in 1936 totaled 106,652,000 gallons, or 39 percent higher than in 1935. Exports also rose—from 4,237,000 gallons in 1935 to 4,897,000 gallons in 1936. The increase in sales in 1936 appears to have resulted from a general expansion; butane and propane, the two most important kinds of gas, maintained their relative positions, and the division between domestic or "bottled-gas" sales and industrial uses remained virtually unchanged.

Marketed production of liquefied petroleum gases in the United States, 1922-36

Year	Gallons	Year	Gallons	Year	Gallons	Year	Gallons

¹ Revised figures.

The economic history of the liquefied-gas industry in 1936 has been summarized as follows:²

A review of the market requirements for the various liquefied gases shows that sales of propane increased from 26,814,000 gallons in 1935 to 36,502,000 gallons in 1936, a gain of 36.1 percent. Deliveries of butane, which are larger in volume than any of the other liquefied petroleum gases, increased to 47,455,000 gallons in 1936, or 39.2 percent over the 1935 total of 34,084,000 gallons. Sales of propane-butane mixtures, ranking third in relative volume, gained 49.1 percent in 1936. The demand for pentane in 1936 was limited to 2,575,000 gallons, a quantity only slightly above the 1935 deliveries.

The industrial use of liquefied petroleum gases totaled 47,894,000 gallons in 1935 and constituted 62.3 percent of the market demand, while the comparative total for 1936 is 67,267,000 gallons or 63.1 percent of all deliveries. A tabulation of sales records, as reported to the Bureau of Mines, shows that the 1936 total is divided as follows: Industrial fuel 40,140,000 gallons, chemical manufacturing 14,445,000 gallons, internal-combustion-engine fuel 12,476,000 gallons, and miscellaneous uses 206,000 gallons. The item covering the use of liquefied petroleum gases for motor fuel is of special interest, as it is the first time that this demand has been segregated in this annual survey. Sales of liquefied petroleum gases for domestic or "bottled gas" purposes accounted for 28.1 percent of the total demand in 1936. The quantity reported under this classification is 30,014,000 gallons, a gain of 40.4 percent over 1935 deliveries. Liquefied petroleum gases purchased by gas companies showed an increase of 23.6 percent in 1936, totaling 9,371,000 gallons compared with 7,581,000 gallons in 1935.

Propane, because of its high volatility, is sold principally for domestic purposes, or for cooking and lighting in homes where gas from gas-company mains is not available. This demand of 24,423,000 gallons accounted for two-thirds of the total sales of propane in 1936. Propane is of secondary importance as an industrial fuel, and a small amount is used as a raw material in chemical manufacturing. Sales of propane for industrial fuel and chemical use were reported as 11,030,000 gallons in 1936. Less than 1 million gallons of propane were purchased by gas-manufacturing companies in 1936. Butane, less volatile than propane, has a higher B. t. u. value per gallon, hence it is used chiefly as an industrial fuel, there being 28,553,000 gallons of butane (60.2 percent of total deliveries) sold under this caption in 1936, including a small quantity going to chemical plants for raw material. Distributors reported that 9,622,000 gallons of butane were used as fuel in internal-combustion engines in 1936, a demand confined largely to the Pacific Coast area. Deliveries of butane to gas companies, which declined from 5,064,000 gallons in 1934 to 5,042,000 gallons in 1935, registered a gain in 1936, when a total of 6,227,000 gallons was reported under this classification. Domestic uses of butane increased over 100 percent in 1936, showing 2,956,000 gallons compared with 1,353,000 gallons in 1935. Propane-butane mixtures are sold largely to chemical plants for raw material, and a minor quantity is consumed as industrial fuel. The domestic and the gas-manufacturing demand, respectively, for propane-butane mixtures was approximately 2 million gallons in 1936, while about 2,700,000 gallons were sold for motor fuel in the same period.

The American Gas Association has supplied the following review regarding plants distributing liquefied petroleum gases in the United States in 1936.

"At the end of 1936, liquefied petroleum gas was being delivered through mains to consumers in 178 communities in 30 States by 72 companies supplying 31,300 customers.

Butane-air gas with heating value ranging from 520 to 900 B. t. u. per cu. ft. was supplied to 124 communities in 28 States by 60 companies.

² Coumbe, A. T., Sales of Liquefied Petroleum Gases Continue to Expand in 1936: Min. Market Rept. 643, Bureau of Mines, 1937, 4 pp.

A mixture of undiluted butane and propane gas with a heating value of 2,800 to 3,000 B. t. u. per cu. ft. was supplied to 14 communities in California and Nevada by 6 companies. Undiluted propane gas with a heating value of 2,550 B. t. u. per cu. ft. was supplied to 40 communities in Maryland, Minnesota, New Jersey, North Dakota, Virginia, and Wisconsin by 6 companies."

Bulk shipments totaled 82,575,000 gallons in 1936 or 77.4 percent of the total movement of liquefied petroleum gases into consumption, compared with 61,457,000 gallons or 80.0 percent of the 1935 marketed demand. Cylinder and drum deliveries were relatively greater in 1936, 22.6 percent of the liquefied-petroleum-gas sales being handled in these containers compared with 20.0 percent in 1935. The volume of cylinder shipments increased from 15,398,000 gallons in 1935 to 24,077,000 gallons in 1936.

There were 32 distributors who reported their 1936 sales of liquefied petroleum gases to the Bureau of Mines compared with 30 who cooperated in the 1935 study. Eleven out of the 1936 total operated in the Pacific Coast area.

Marketed production of liquefied petroleum gases by uses, methods of transportation, and regional distribution, 1935-36

The carbon-black industry experienced a record-breaking year in 1936, with new highs for production, domestic sales, and exports. (See fig. 79.) In addition stocks at the plants were reduced mate-

FIGURE 79.—Carbon-black production, stocks, and deliveries, 1919-36.

rially, reaching approximate working-stock levels at the close of the year. Prices remained remarkably uniform throughout the year; the average plant value increased slightly to just under 4 cents per pound, and the average export value remained unchanged at nearly 1 cent more. Threats to the prevailing stability were evidenced in repeated reports that consumers were storing stocks in anticipation of labor troubles and that the Texas Legislature was about to impose a heavy tax on carbon black. Anticipated increases in stocks based on the expectation of prolonged labor disturbances in the rubber industry failed to materialize, and the consensus of opinion was that the industry actually used most of its 30-percent increase in purchases (1936 over 1935) during 1936. The Texas Legislature imposed a tax of about 3 percent on carbon-black production late in the year, but this tax was partly neutralized by downward revisions in freight rates early in 1937.

Production, by States, districts, and months.—An increase in production of carbon black in Oklahoma and Wyoming was virtually offset by a decline in Louisiana; in other words, most of the 60,000,000-pound increase in national output was recorded in Texas, more specifically in the Texas Panhandle, which was credited with nearly 80 percent of the total production of the United States in 1936.

The competition of domestic demand for gas in Louisiana continued to restrict operations in that State, and production declined from 64,875,000 pounds in 1935 to 59,201,000 in 1936. A number of units in Louisiana were dismantled and moved to Texas; this is reflected in the decline from 19 operating plants in Louisiana in 1935 to 16 in 1936.

Although the center of the industry has been moving closer and closer to the Panhandle, primarily because of the comparative cheapness of the gas in that area, a possible spreading out of production in the not too distant future is indicated. First, the supply of residue gas from "stripper" plants in the Panhandle has been curtailed; and, second, production in Oklahoma and Wyoming, the other producing States, increased about 40 or 50 percent in 1936 over 1935.

¹ Monthly figures obtained by allocating the Bureau's annual total proportionately to the Association's monthly data.

According to estimates based on the monthly figures of the National Gas Products Association, the output of carbon black increased more or less steadily in 1936, reaching nearly 38,000,000 pounds in December.

Methods and yields.—Although the channel process continued to be the primary method of manufacturing carbon black, there was a slight gain in the relative importance of the "other processes" in 1936. Thus the output of channel black increased from 316,284,000 pounds in 1935 to 366,876,000 in 1936, a gain of 16 percent, whereas production by other processes, the Lewis, roller, "special", and thermatomic, increased from 36,465,000 pounds in 1935 to 44,469,000 in 1936, or 22 percent.

⁴ Eastland County included with Stephens County.

Carbon-black manufacture continued to account for a material part of the total consumption of natural gas; the quantity burned in 1936

(283,421,000,000 cubic feet) comprised about 13 percent of the estimated total consumption, the same ratio as in 1935. Although the gain in production of carbon black by "other processes" usually indicates an increase in output of high-yield retort blacks and hence a gain in the national yield, the reverse held true in 1936, and the average yield declined from 1.46 to 1.45 pounds per thousand cubic feet.

Number and capacity of plants.—Despite continuation of stable economic conditions the total number of plants remained 54 in 1936, the same as in 1935. A loss of three plants in Louisiana was balanced by the addition of two in the Panhandle and the renewal of operations at one in Oklahoma. The concentration of plants among fewer operators continued in 1936, when there were only 20 compared with 21 in 1935 and 25 in 1934.

Apparently all the units dismantled in Louisiana were not set up in the Panhandle, as the total daily capacity of all plants declined from 1,452,125 pounds in 1935 to 1,432,095 in 1936. This decline in capacity plus the increase in output, indicates an advance in the operating ratio (daily production divided by daily capacity) from 67 percent in 1935 to the comparatively high point of 78 percent in 1936.

Producers.—The reported changes in the list of carbon-black producers were as follows: The Keystone Carbon Co. and the Texas-Louisiana Producing & Carbon Co. went out of business in Louisiana; the Cabot Carbon Co. renewed operations in Oklahoma; the Columbian Carbon Co. took over the Western Carbon Co.; and the Reliance Carbon Co., Inc., began operations in Texas.

DEMAND

Total deliveries.—The demand for carbon black continued in record-breaking proportions in 1936, as the equivalent of all the record output

FIGURE 80.—Production and consumption of carbon black, 1930-36.

was sold, and in addition substantial amounts were withdrawn from stocks. Total sales rose from 387,536,000 pounds in 1935 to 467,736,000 in 1936, a gain of 21 percent; of the latter, 313,018,000 pounds (67 percent) were sold in the United States and 154,718,000 pounds (33 percent) exported. Although exports reached a new high level in 1936, their percentage of total sales declined.

Domestic consumption.—Of total domestic sales in 1936, 278,018,000 pounds (89 percent) were consigned to rubber companies, 17,787,000 pounds (6 percent) to ink companies, 6,914,000 pounds (2 percent) to paint companies, and 10,299,000 pounds (3 percent) to companies producing miscellaneous products. These data indicate a continued increase in the importance of the rubber trade for, although sales to each of the other three classes increased in 1936 compared with 1935, their respective percentages of total domestic sales dropped. (See fig. 80.)

In accounting for the 30-percent gain in indicated demand by the rubber trade for carbon black, E. G. Holt of the Bureau of Foreign and Domestic Commerce has kindly supplied pertinent rubber statistics. According to Holt, the total consumption of crude and reclaimed rubber in the United States increased from 609,000 long tons in 1935 to 708,000 in 1936, a gain of 16 percent; of the latter figure, 575,000 long tons was crude rubber and 133,000 reclaimed rubber. The output of automobile casings, which showed a comparative lag in 1935, increased materially in 1936, when production was 58,098,000, or 19 percent higher than in 1935. Sales of motor vehicles increased from 3,946,934 in 1935 to 4,454,535 in 1936, a gain of 13 percent.

The material increase in the production of casings and the consumption of crude rubber in 1936 over 1935 accounts for the major portion of the 30-percent gain in sales of carbon black to rubber companies. Part of the remainder might be accounted for by increases in consumers' stocks, although the most likely explanation is that the average size of casings continued to increase. The production of tires with white-rubber sides may have increased, although it is doubtful if this development appreciably affected the average consumption of carbon black per casing.

According to Holt, the apparent consumption of crude rubber in the world was 1,051,000 long tons in 1936, a gain of 12 percent over 939,000 long tons in 1935; as the gain in the United States was 17 percent in the same period, the paramount position of this country in the use of rubber was necessarily somewhat strengthened.

Sales of carbon black to ink companies increased from 15,177,000 pounds in 1935 to 17,787,000 in 1936, or 17 percent. This advance reflects chiefly the gain of 12 percent in domestic consumption of newsprint reported by the Bureau of Foreign and Domestic Commerce as 3,272,000 short tons in 1935 and 3,658,000 in 1936.

Sales of carbon black to paint companies rose from 6,550,000 pounds in 1935 to 6,914,000 in 1936, or 6 percent. Data for 1936 on the production of black paints are lacking, but it may safely be concluded that this branch of the paint industry shared the general pick-up in business, in which the increased use of carbon black by the automotive industry played a prominent part.

Sales of carbon black for miscellaneous purposes, which increased unaccountably in 1935, advanced farther in 1936, when the total was 10,299,000 pounds compared with 9,916,000 pounds the preceding year.

The loss of carbon black incurred in handling at the plants was a negligible factor in distribution in 1936; only 113,000 pounds were so reported.

*Exports and imports.*¹—Exports of carbon black established a new high record in 1936, when 154,718,398 pounds were shipped abroad, compared with 142,184,802 pounds in 1935 and 152,286,178 in 1933, the previous peak. The declared value of exports in 1936 was \$7,250,704, an average of 4.69 cents per pound, the same average as in 1935.

The United Kingdom continued to purchase the largest amount of carbon black from the United States; in 1936 it took 46,956,730 pounds compared with 38,982,227 in 1935. France and Germany again exchanged rank as purchasers; exports to France increased

¹ Figures on exports and imports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

about 7,000,000 pounds to nearly 27,000,000 pounds in 1936, and exports to Germany declined about 7,000,000 pounds to just over 16,000,000. Exports to Italy, another nation that has been increasing its stocks of tires as part of its defense program, declined materially in 1936, but exports to Japan continued to increase. The monthly record of exports in 1936, like that for production, trended upward, with the largest monthly total, 18,735,875 pounds, in December. Exports followed much the same domestic channels in 1936 as in 1935; Galveston consolidated its position as the leading shipping port, and New Orleans continued to outrank the Michigan customs district for second place.

Imports of "gas black and carbon black", as reported by the Bureau of Foreign and Domestic Commerce, totaled only 120 pounds valued at \$8 in 1936; and imports of acetylene black, superior to carbon black in certain uses, totaled 1,162,215 pounds valued at \$119,564.

STOCKS

Stocks of carbon black at the plants, which rose to unwieldy proportions from 1929 to 1931, were reduced materially in 1936 in spite of the record-breaking output. During 1936 stocks declined from 136,086,000 to 79,582,000 pounds, at which point they represented

only about a 2-month supply. Data on consumers' and brokers' stocks are not available, but it is doubtful if either class increased materially, in spite of threats of serious labor troubles. However, stocks of carbon black did accumulate as finished goods in 1936, as the number of casings in storage increased approximately 4,000,000 during the year.

PRICES AND VALUES

Carbon-black prices changed little in 1936; the average plant value increased only 0.02 cent per pound over 1935, and with two minor exceptions prices for the various zones and grades established under the code remained unchanged. The average value at the plants in 1936 was 3.92 cents per pound compared with 3.90 cents in 1935. In response to inquiries as to what this plant value covers, the Bureau requested producers to give their definitions in reporting for 1936. Although the replies varied considerably, depending on how the charges for freight, special crating, commissions, and discounts were handled, it appears that virtually all producers reported on the basis of average delivery price minus average freight and that most of them deducted unusual expenses, such as export packing costs. Additional attempts will be made to obtain uniformity in reporting plant values.

Quoted prices on various grades of carbon black, 1935-36, in cents per pound

Zone G: Mexico.

HELIUM

By H. S. KENNEDY and C. W. SEIBEL

SUMMARY OUTLINE

	Page		Page
Year's developments for use of helium.....	1119	Amarillo helium plant.	1120
Cliffside gas field.....	1120	Salient statistics.....	1121

The Bureau of Mines is concerned with the production of a safe lifting-gas for airships. If lighter-than-air craft are to offer the real assurance of safety necessary for their successful use they must depend on a noninflammable gas for their buoyancy. The only gas having the desired requirements of both lightness and noninflammability is helium. Hydrogen gas, which is about 8 percent more buoyant than helium and has been used extensively as the lifting agent for airships, is extremely explosive. The accidental ignition of hydrogen has been responsible for disasters to various airships in the past, the destruction of the *Hindenburg* being the most recent example.

The airships operated by the Army and Navy and the Goodyear Co. are provided with helium, but all foreign-owned aircraft have depended on the highly inflammable hydrogen for their buoyancy. This situation has existed because the United States is the only nation, so far as known, having sufficient reserves of helium to develop a supply for aeronautics. Army and Navy operations are limited to to nonrigid airships at present; in addition, the Army has a project under development for two motorized balloons.

The Government demand for helium was reduced in 1936 because the Army and Navy operated only nonrigid airships during the year. The President, however, approved the leasing of 1,000,000 cubic feet of helium produced at the Amarillo plant to the Goodyear-Zeppelin Corporation, which operates a fleet of five commercial nonrigid airships. The purpose of leasing the Government helium was to foster the development of commercial lighter-than-air craft and to encourage the training of airship pilots.

In 1936 the Bureau of Mines again supplied about 25,000 cubic feet of helium to the United States Public Health Service, which is co-operating with certain hospitals in the medical use of helium. Helium mixed with oxygen is being used widely in the treatment of asthma; also it is reported to have favorable results in alleviating other respiratory diseases. Investigations are being conducted on the use of helium as a substitute for air in the pneumothorax treatment of tuberculosis, on the theory that it will decrease the frequency of the treatments and may have some effect on the tubercle bacillus. The use of helium-oxygen mixtures for the treatment of atelectasis is

also showing favorable results; the defective expansion of the air cells of the lungs of new-born children is corrected by this treatment.

Cliffside gas field.—The Government Cliffside helium reserve of 50,000 acres in Potter County, Tex., comprising a whole gas structure owned in fee, was operated in 1936 to supply helium-bearing natural gas to the Amarillo helium plant. The field produced 294,838,000 cubic feet of natural gas during the fiscal year 1936, which made a cumulative total of 4,398,659,000 cubic feet of natural gas produced from the field from May 16, 1929 to June 30, 1936. The average rock pressure of the field indicated that the formation pressure in the vicinity of the wells remained constant for the year and represents a decline of only about 2 percent of the total original reserve.

Amarillo helium plant.—The Bureau of Mines helium plant near Amarillo, Tex., operated intermittently during the year. The total production for the fiscal year 1936 was 4,663,355 cubic feet of helium, which represents a considerable reduction over the 1935 production of 10,218,480 cubic feet. Demand for helium was curtailed because the Army and Navy now operate only nonrigid airships. The Amarillo plant has an annual capacity of 24,000,000 cubic feet of helium, and Bureau engineers estimate that the gas could be produced at a net cost to the Government of about \$4 per thousand cubic feet if the plant could be operated at its capacity.

From the beginning of operations in May 1929 to June 30, 1936, the plant has produced 73,350,975 cubic feet of helium with an expenditure of \$848,805.30 for plant and gas-field operation—an all-time average gross operating cost of \$11.57 per thousand cubic feet of helium. The sale of residue gas returned \$200,356.02 to the National Treasury during this period, so that the net Government expenditure was \$648,449.28, or \$8.84 per thousand cubic feet of helium produced.

Government helium production and costs, April 1921 to June 1936

¹ Production from the Fort Worth plant represents volume of airship gas produced, which had an average helium purity of 94 to 95 percent. Production from the Amarillo plant represents actual helium in the airship gas of better than 98-percent purity produced by that plant. Therefore, the advantage of the Amarillo plant from standpoint of cost is about 5 percent greater than a direct comparison of the figures indicates.

² Gross operating costs for the Fort Worth plant represent expenditures in operating and maintaining the plant, including current expenditures for natural gas. The Government did not own the gas field that supplied the Fort Worth plant, so there was no return from sale of residue. Gross operating cost for the Amarillo plant represents expenditure in operating and maintaining both the plant and the Government-owned gas properties. This gross operating cost at Amarillo is a measure of the amount that must be available to the Bureau of Mines for current expenditure. Returns from sale of residue gas must be deposited to credit of miscellaneous receipts of the Treasury and therefore are not available for expenditure by the Bureau. As the net operating cost is computed by subtracting current returns from current expenditures, it is a measure of the net withdrawal of funds from the Treasury for operation and maintenance.

³ Costs at the Fort Worth plant are based on compilations by the Bureau of Efficiency from records of the Navy Department and the Bureau of Mines. (Report of Bureau of Efficiency in hearing on Amarillo helium plant before the Committee on Mines and Mining, House of Representatives, 71st Cong., 2d sess., p. 210.) The costs do not include depreciation or depletion, and those for period of Navy jurisdiction do not include cost of Washington administration.

⁴ Plant closed in 1922 from January to September, inclusive, because of lack of funds.

⁵ Compiled from Bureau of Mines records. The costs do not include depreciation or depletion.

⁶ Plant shut down entire months of December 1929 and February 1930. Stand-by costs for these 2 months were \$19,181.14.

ASPHALT AND RELATED BITUMENS

Recovery in the asphalt industry is indicated by production and demand in 1936 which exceeded the records of the previous peak years, 1927 and 1929. To meet an increase of 28 percent in total demand, domestic and foreign, petroleum refineries in the United States enlarged their output of asphalt only 24 percent from 1935 to 1936. Accordingly, stocks of asphalt at the refineries were reduced 15 percent during the year. Imports—relatively insignificant—were more than halved. As domestic requirements constituted 96 percent of the total demand, the decrease of 15 percent in exports had little effect on the national market.

Larger Federal and State allotments of funds to highways supplied the principal impulse to the accelerated demand for manufactured and native asphalts from 1935 to 1936. Increased construction of hard-surfaced roads and streets fostered a 36-percent advance in sales of paving asphalt and a 74-percent advance in sales of natural rock asphalt. Similarly, increased construction of lighter-type highways is indicated by an advance of 44 percent in sales of cut-back asphalts, 31 percent in sales of asphalt emulsions, and 21 percent in sales of road oil. Continued revival in building construction caused an 18-percent increase in sales of roofing asphalt and flux and accelerated sales of waterproofing asphalt and flux, and asphaltic paints and varnishes.

Greater demand for paving and roofing asphalts raised the prices of these products and emulsions, in contrast to the downward trend in prices of other varieties of manufactured asphalt and bituminous rock. Sales values of gilsonite and of paints and varnishes manufactured from petroleum asphalt were lower in 1936 than in 1935. Demand from the electrical industry raised the sales value of asphaltic molding compounds in 1936.

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

NATIVE ASPHALT AND BITUMENS

Bituminous rock.—Revival of highway construction caused sales of bituminous rock by producers to increase from 314,109 short tons valued at \$1,449,406 in 1935 to 547,333 tons valued at \$2,420,792 in 1936. Rock-asphalt operators in Kentucky, Alabama, and Ohio sold 109,179 tons valued at \$650,927 in 1935 and 178,208 tons valued at \$1,054,265 in 1936. Producers in Texas, Oklahoma, and New Mexico sold 185,013 tons valued at \$726,801 in 1935 and 333,243 tons valued at \$1,245,442 in 1936. Gains were also made in Kansas, Missouri, and California.

Gilsonite and wurtzilite.—Increased demand for paints and varnishes and for electrical fittings brought higher prices for gilsonite. The value of gilsonite sales by producers in northeastern Utah increased 10 percent—from \$696,601 in 1935 to \$767,066 in 1936. The quantity sold, however, decreased 9 percent—from 33,227 short tons in 1935 to 30,227 tons in 1936, exports dropping rather than domestic sales. Sales of wurtzilite increased from 61 short tons valued at \$2,754 in 1935 to 77 tons valued at \$6,137 in 1936.

Exports.—Decreased demand from Europe, notably Germany, the United Kingdom, and Italy, caused exports of natural asphalt and bitumen, unmanufactured, to drop from 19,229 short tons valued at \$709,709 in 1935 to 14,240 tons valued at \$528,066 in 1936. Of the exports, 67 percent went to Europe in 1936 compared with 72 percent in 1935, 13 percent to Canada compared with 8 percent in 1935, 6

percent to South America compared with 12 percent in 1935, and 11 percent to Asia compared with 5 percent in 1935.

MANUFACTURED OR PETROLEUM ASPHALT

Domestic demand for asphalt increased from 3,027,648 short tons in 1935 to 3,962,257 in 1936. Exports of petroleum asphalt decreased from 222,825 tons in 1935 to 190,503 in 1936. In response to the increase of 902,287 tons in total demand, domestic and foreign, refinery production of asphalt increased from 3,287,003 tons in 1935 to 4,065,622 in 1936. At the same time stocks of asphalt at petroleum refineries were reduced 65,540 tons in 1936 compared with an increase of 90,502 tons in 1935. Imports of asphalt and bitumen decreased from 53,972 tons in 1935 to 21,598 in 1936.

Production.—Of the 1936 production of petroleum asphalt, 43 percent was made from foreign crude oil imported from Venezuela and Mexico compared with 45 percent manufactured from foreign crude in 1935. Runs to stills of foreign petroleum increased 6 percent—from 32,131,000 barrels in 1935 to 33,933,000 barrels in 1936. However, since most of the foreign oil run to stills in 1936 comprised heavy Venezuelan and Mexican crudes, the production of asphalt from foreign oil increased 17 percent—from 1,485,225 short tons in 1935 to 1,738,255 in 1936. Eighty-five percent of the asphalt manufactured

Asphalt and asphaltic material (exclusive of road oil) sold at petroleum refineries in the United States, in 1936, by varieties

1 DEFINITIONS

Paving asphalt.—Refined asphalt and asphaltic cement, fluxed and unfluxed, produced for direct use in the construction of sheet asphalt, asphaltic concrete, asphalt macadam, and asphalt block pavements, and also for use as joint filler, in brick, block, and monolithic pavements.

Roofing asphalt.—Asphalt and asphaltic cement used in saturating, coating, and cementing felt or other fabric and in the manufacture of asphalt shingles.

Waterproofing asphalt.—Asphalt and asphaltic cement used to waterproof and dampproof tunnels, foundations of buildings, retaining walls, bridges, culverts, etc., and for constructing built-up roofs.

Briquetting asphalt.—Asphalt and asphaltic cement used to bind coal dust or coke breeze into briquets.

Mastic and mastic cake.—Asphalt and asphaltic cement for laying foot pavements and floors, waterproofing bridges, lining reservoirs and tanks, capable of being poured and smoothed by hand troweling.

Pipe coatings.—Asphalt and asphaltic cement used to protect metal pipes from corrosion.

Molding compounds.—Asphalts used in the preparation of molded composition, such as battery boxes, electrical fittings, push buttons, knobs, handles, etc.

Miscellaneous uses.—Asphalt and asphaltic cement used as dips, and in the manufacture of acid-resisting compounds, putty, saturated building paper, fiber board, and floor coverings, and not included in the preceding definitions.

Flux.—Liquid asphaltic material used in softening native asphalt or solid petroleum asphalt for paving, roofing, waterproofing, and other purposes.

Cut-back asphalts.—Asphalts softened or liquefied by mixing them with petroleum distillates.

Emulsified asphalt and fluxes.—Asphalts and fluxes emulsified with water for cold-patching, road laying and other purposes.

Other liquid products.—Petroleum asphalt, exclusive of fuel oil used for heating purposes, not included in the preceding definitions.

in East coast refineries in 1936 and 62 percent of that manufactured in Gulf coast refineries was made from foreign crude. At the same time, the production of asphalt from domestic crudes increased (especially in the Indiana-Illinois-Kentucky, Oklahoma-Kansas-Missouri, interior Texas, and Rocky Mountain districts) from 1,801,778 short tons in 1935 to 2,327,367 tons in 1936. The total refinery output of asphalt in 1936 included 196,784 tons of other petroleum products blended with the asphalt to produce commercial varieties of the required consistency.

Stocks.—Stocks of asphalt held at petroleum refineries decreased 65,540 tons—from 429,739 tons on December 31, 1935, to 364,199 on December 31, 1936. Only the Gulf coast refineries of Texas furnished an exception to the general reduction in inventories.

Sales.—Sales of asphalt by petroleum refineries increased in quantity from 3,142,602 short tons in 1935 to 4,074,745 tons in 1936 and in value from \$31,354,678 in 1935 to \$41,144,579 in 1936. The average sales value per short ton increased from \$9.98 in 1935 to \$10.10 in 1936.

The increase in sales was general but was greatest in the East Coast district, where 1,300,924 tons of asphalt were sold in 1935 and 1,703,768 in 1936. There were also notable increases in asphalt sales in the Indiana-Illinois-Kentucky district (646,006 tons in 1935 and 777,694 in 1936), in the Oklahoma-Kansas-Missouri district (93,102 tons in 1935 and 208,769 in 1936), in the Gulf Coast districts of Texas and Louisiana (315,015 tons in 1935 and 455,243 in 1936), and in the Rocky Mountain district (75,715 tons in 1935 and 125,820 in 1936). Of the major asphalt-producing districts California had the lowest proportional increase—from 443,181 tons in 1935 to 489,772 in 1936.

Nearly three-fifths of the petroleum asphalt sold in the United States in 1936 was used to surface streets and highways. An indicated increase of 10 percent in the total funds, Federal, State, and municipal, available for highway construction made possible an increase of 39 percent in the tonnage of asphalt sold primarily for paving. The gain was greater in the semisolid and liquid asphalts, which are used primarily for the construction of the lighter types of highway; nevertheless, sales of paving asphalt, which are used for the higher types of consumption, were 36 percent greater in 1936 than in 1935.

All available statistical information points to an increase in rural highway construction in 1936. The State highways built, as reported by the Association of State Highway Officials, increased from 25,853 miles in 1935 to 32,635 in 1936. The length of highways completed under the supervision of the Bureau of Public Roads, through its use of Public Works, Emergency Relief, and Federal-aid funds, increased from 13,017 miles in 1935 to 18,390 in 1936. At the end of 1936, 8,003 miles were under construction and 2,635 had been approved for construction compared with 7,766 miles under construction and 5,903 approved for construction at the end of 1935. According to the Bureau of Public Roads, employment on Federal and State highways, both for construction and maintenance, increased from 301,660 man-months in 1935 to 335,991 in 1936.

In 1936, as in 1935, Federal funds financed by far the greater part of the highway mileage constructed. Federal and State funds available for street and highway construction were 10 percent greater in 1936 than in 1935. The total value of highway contracts awarded and

force-account work undertaken, financed by Federal funds, increased from \$353,967,106 in 1935 to \$367,574,865 in 1936, and contract awards financed by State funds, as reported to the Bureau of Labor Statistics, increased even more in proportion—from \$52,782,494 in 1935 to \$80,508,252 in 1936.

According to the Bureau of Labor Statistics the value of contracts for street paving awarded and force-account work begun in cities with populations exceeding 150,000 totaled \$12,847,082 in 1935 and \$12,803,065 in 1936. This decrease of 0.3 percent in money expended for street paving in the larger cities represented a decline of approximately 6 percent in the yardage of pavement laid, when allowance is made for the increase, according to the cost index of the Engineering News Record, of about 6 percent in construction costs from 1935 to 1936.

Bituminous types constituted 24 percent of the total highway mileage reported by the Association of State Highway Officials for 1936 compared with 20 percent in 1935. Of the mileage in 1936 48 percent comprised light types of construction while 18.1 percent comprised mere grading and draining operations (17.5 percent in 1935). Asphaltic types of construction accounted for 70 percent of the total hard-surfaced mileage in 1935 and 71 percent in 1936.

Increased construction of high-type, hard-surfaced roads is indicated by an increase in sales of paving asphalt of less than 200 penetration (from 877,466 tons in 1935 to 1,190,705 in 1936). The increase was general except for the Indiana-Illinois-Kentucky district, with a reduction from 96,338 tons in 1935 to 90,263 in 1936. The greatest gain was in sales by East coast refineries (from 433,454 tons in 1935 to 611,478 in 1936). Gulf coast refineries of Texas and Louisiana increased their sales of paving asphalt from 118,059 tons in 1935 to 173,716 in 1936. Refineries of northern Louisiana and Arkansas continued to increase their sales of paving asphalt (from 37,232 tons in 1935 to 51,695 in 1936). Rocky Mountain refineries, which sold only 3,742 tons of paving asphalt in 1935, sold 30,539 tons in 1936. There were smaller increases in the Oklahoma-Kansas-Missouri district and in interior Texas. California showed the smallest proportional increase in sales of paving asphalt (from 137,340 tons in 1935 to 146,165 in 1936).

Sales of paving asphalt made from foreign petroleum increased from 457,695 tons in 1935 to 583,317 in 1936, and sales of paving asphalt made from domestic crude increased from 419,771 tons in 1935 to 607,388 in 1936.

There was a parallel increase in sales of paving flux (from 113,066 tons in 1935 to 153,931 in 1936). The principal gains occurred in the east coast district, in coastal Texas and Louisiana, and in California.

An even greater proportional increase in the construction of the lighter types of highway is indicated by a gain in the sales of semi-solid and liquid asphalts used primarily for paving. Sales of cut-back asphalts increased from 707,953 tons in 1935 to 1,021,290 in 1936 and of emulsified asphalts by petroleum refineries from 39,861 tons in 1935 to 53,045 in 1936.

Sales of cut-back asphalts gained most in the east coast district, where refineries sold 307,095 tons in 1935 and 384,333 in 1936; next ranked the Oklahoma-Kansas-Missouri district, where refineries increased their sales of cut-backs from 69,417 tons in 1935 to 139,004 in 1936 and in third place stood the Illinois-Indiana-Kentucky district, where refineries sold 117,608 tons in 1935 and 166,268 in 1936. In

Louisiana and Arkansas sales of cut-back asphalts increased from 75,970 tons in 1935 to 121,958 in 1936. The highest proportional gain took place in California, where 33,094 tons of cut-backs were sold in 1935 and 82,457 in 1936.

Petroleum refineries sold 39,861 short tons (9,390,633 gallons) of asphalts and fluxes emulsified with water valued at \$359,650 in 1935 and 53,045 tons (12,496,579 gallons) valued at \$567,886 in 1936. In addition, 33,248,105 gallons valued at \$3,434,877 were sold in 1935 by industrial companies that purchased asphalt from petroleum refineries and 43,464,787 gallons valued at \$3,976,345 in 1936. Accordingly, total sales of emulsified asphalts and fluxes increased in quantity from 42,638,738 gallons in 1935 to 55,961,366 in 1936 and in value from \$3,794,527 in 1935 to \$4,544,231 in 1936.

As a result of the pronounced increase in paving demand only 26 percent of the asphalt sold in 1936 was used in the manufacture of prepared roofing compared with 29 percent in 1935. Nevertheless, continued revival in building construction caused sales of roofing asphalt and roofing flux to increase 18 percent in quantity (from 911,216 short tons in 1935 to 1,074,277 in 1936) and 23 percent in value (from \$8,913,628 in 1935 to \$10,957,858 in 1936). This gain generally paralleled the increase, reported by the Bureau of the Census, of 24 percent in sales of prepared roofing (from 26,050,151 squares in 1935 to 32,218,862 in 1936) and the increase, reported in the Survey of Current Business, of 21 percent in shipments of dry roofing felt (from 221,123 short tons in 1935 to 267,742 in 1936). Sales of roofing asphalt and flux increased principally in the east coast district (from 353,349 tons in 1935 to 459,337 tons in 1936) and in the Indiana-Illinois-Kentucky district (from 280,314 tons in 1935 to 329,054 tons in 1936). Smaller gains in the Oklahoma-Kansas-Missouri district, in inland Texas, in the Gulf coast of Louisiana and Texas, and the Rocky Mountain district offset a major decline in California (from 106,265 tons in 1935 to 68,139 in 1936) and smaller decreases in the Appalachian district and in northern Louisiana and Arkansas.

Building construction was responsible for the demand for 6 percent of the asphalt sold in 1935 and 5 percent of that sold in 1936 in the form of waterproofing asphalt and flux; mastic and mastic flux; and paints, enamels, japans, and lacquers. Such sales increased 11 percent—from 200,203 tons in 1935 to 222,073 in 1936. They did not keep pace, however, with the increase of 62 percent in floor space of building contracts awarded, as compiled for 37 States by the F. W. Dodge Corporation. Contracts for residential building increased 64 percent, while contracts for nonresidential structures increased 60 percent.

Although the production of coal briquets increased only 31 percent (from 860,707 short tons in 1935 to 1,124,973 in 1936) sales of briquetting asphalt increased 54 percent (from 40,945 tons in 1935 to 63,185 in 1936). Plants using asphalt as a binder accounted for a larger proportion of the total output in 1936 than in 1935.

Despite the increase of only 17 percent in domestic consumption of rubber, crude and reclaimed, reported in the Survey of Current Business, sales of asphalt for blending with rubber increased 53 percent (from 15,131 tons in 1935 to 23,137 in 1936).

Notwithstanding continued improvement in the demand for electrical equipment, sales of asphaltic molding compounds decreased from 14,670 tons in 1935 to 14,059 in 1936.

The greater demand for paving and roofing asphalts and fluxes raised the prices of these products in contrast to the downward trend in prices of other varieties. The average sales value of paving asphalt at the refinery increased from \$10.03 per short ton in 1935 to \$10.27 in 1936; of roofing asphalt, from \$10.70 in 1935 to \$10.88 in 1936; and of roofing flux, from \$7.71 in 1935 to \$7.93 in 1936. Similarly, the average value of emulsified asphalt sold by petroleum refineries rose from \$9.02 in 1935 to \$10.71 in 1936. Revival in the electrical industry raised the sales value of asphaltic molding compounds from \$10.97 per ton in 1935 to \$11.91 in 1936. On the other hand, the average sales value of waterproofing asphalt declined from \$10.87 per short ton in 1935 to \$9.59 in 1936; of cut-back asphalts, from \$10.46 in 1935 to \$10.31 in 1936; and of paints, enamels, japons,

FIGURE 81.—Relation of indicated monthly demand for asphalt, 1927-36, to long-time trend, 1909-36, multiplied by seasonal factors. The long-time trend is expressed by the formula, $\log Y = 1.121409 + 0.906962 \log X$, in which Y equals the average monthly demand for petroleum and lake asphalt during each year and X equals the number of years, beginning with 1907 as zero. The coefficient of correlation for this formula is 0.954. The seasonal factors were calculated for 1927-36 by the method of link relatives.

and lacquers from \$11.86 in 1935 to \$10.83 in 1936. The greatest decline was in the sales value of pipe coatings—from \$16.41 in 1935 to \$12.21 in 1936.

DOMESTIC DEMAND

The indicated domestic demand for petroleum asphalt (including small quantities of imported lake asphalt and grahamite) was 31 percent greater in 1936 than in 1935, increasing from 214,116 short tons a month in 1934 and 252,304 in 1935 to 330,188 in 1936.

In terms of the long-time trend (revised to include 1936) the indicated demand exceeded by 18 percent the expected demand for 1936, whereas it was 7 percent below the expected demand for 1935; that is, if the national demand had continued the average rate of growth it manifested from 1908 to 1936, it would have averaged 253,943 tons a month in 1933, 262,786 tons a month in 1934, 271,602 tons a month

in 1935, and 280,381 tons a month in 1936. Using these averages as a standard of comparison, the indicated demand of 252,304 tons a month in 1935 was 93 percent of the expected demand (271,602 tons), and the indicated demand of 330,188 tons a month in 1936 was 118 percent of the expected demand (280,381 tons). (See fig. 81.)

However, the demand for asphalt is seasonal to a marked degree, reaching its maximum in August and its minimum in February. Normally, 65 percent of the indicated consumption of asphalt occurs in the 6 months from May 1 to October 31; from 1934 to 1936, 69 percent of the annual total was apparently consumed in these months. Consequently, to furnish an adequate standard of comparison the monthly trend values are multiplied by a "seasonal factor" for each month.

The demand for asphalt was lowest in the first quarter of 1936, averaging 90 percent of the revised long-time trend multiplied by seasonal factors compared with 71 percent in the first 3 months of 1935. In the second quarter of 1936 it rose to an average of 107 percent of the expected demand for these months compared with 90 percent during the second quarter of 1935. From July to September 1936 the indicated demand was highest, averaging 137 percent of the expected demand compared with 103 percent in the same months of 1935. In the last quarter of 1936 the indicated demand declined relatively, averaging 122 percent of the expected demand compared with 97 percent in the last 3 months of 1935.

Relation of indicated asphalt demand to basic trend multiplied by seasonal factors, 1935-36

DISTRIBUTION BY RAIL

The tonnage of asphalt (natural, byproduct, or petroleum) terminated by class I railroads in the United States increased from 3,067,182 short tons in 1935 to 4,180,450 in 1936, according to freight-commodity statistics compiled by the Interstate Commerce Commission. The gains were general but were greatest in the area lying between the Ohio and Potomac Rivers and the Great Lakes, in the Southeastern States, and in the Pacific-Rocky Mountain district.

Fifty-seven percent of the asphalt (petroleum, lake, and natural rock) terminated in the continental United States by land carriers in 1936 was delivered to consumers in the Northeastern district lying north of the Potomac and Ohio Rivers and east of the Mississippi and Illinois Rivers. Railroads and motor trucks terminated 2,046,889 short tons of asphalt in this district in 1935 and 2,578,648 in 1936. In the Southeastern district, lying south of the Potomac and Ohio Rivers and east of the Mississippi and Pearl Rivers, land deliveries of asphalt increased from 374,300 tons in 1935 to 596,977 in 1936. In the Southwestern district, lying west of the Mississippi and Pearl Rivers and south of St. Louis, Kansas City, and Amarillo, asphalt deliveries by rail and truck increased from 189,699 tons in 1935 to 265,660 in 1936. In the North Central district, lying between the Great Lakes and the Rocky Mountain front, 424,998 tons of asphalt were delivered in 1935 and 508,640 tons in 1936. In the Pacific-Rocky Mountain district, lying west of Great Falls, Cheyenne, Denver, Albuquerque, and El Paso, the tonnage of asphalt terminated by land carriers increased from 319,855 tons in 1935 to 575,716 in 1936.

Supply and distribution of asphalt (petroleum, lake, and natural rock), exclusive of road oil in continental United States in 1936, by districts, in short tons

	Northeast- ern district	Southeast- ern district	Southwest- ern district	North Cen- tral district	Pacific- Rocky Mountain district

¹ Shipped chiefly by water.

FOREIGN TRADE

Imports.—Imports of asphalt and bitumen into the United States decreased from 53,972 short tons valued at \$544,651 in 1935 to 21,598 tons valued at \$316,144 in 1936. The principal decrease was in receipts of lake asphalt from Trinidad—from 38,824 tons valued at \$403,117 in 1935 to 14,642 tons valued at \$173,679 in 1936. On the other hand, imports of grahamite from Cuba increased from 6,011 tons valued at \$99,667 in 1935 to 6,692 tons valued at \$118,991, in 1936.

Atlantic coast ports (chiefly New York, Baltimore, and Norfolk) received 16,203 tons valued at \$234,765 in 1936 compared with 41,163 tons valued at \$382,858 in 1935 and Gulf coast ports (chiefly Mobile, New Orleans, and Galveston) 5,201 tons valued at \$78,084 in 1936 compared with 12,659 tons valued at \$158,437 in 1935.

Exports.—Exports of petroleum asphalt continued the downward trend which has been evident since 1928, decreasing from 222,825 short tons valued at \$3,370,559 in 1935 to 190,503 tons valued at \$2,835,173 in 1936. Increases in exports to South America and to southern and eastern Africa did not offset the drop in sales to northern and western Europe and to North American countries. Larger shipments to Netherland India did not counteract the general slump in exports of asphalt to eastern Asia and to Australia and New Zealand. Greater refining activity in Europe, Canada, and Japan and increased exports of asphalt from Mexico reduced the foreign market for asphalt produced in American refineries.

¹ Tunisia only in 1936.

Of the petroleum asphalt exported from the United States, 87,955 short tons passed through Gulf coast ports in 1936 compared with 90,214 tons in 1935, 75,229 tons through Pacific coast ports in 1936 compared with 100,503 tons in 1935, and 24,871 tons through Atlantic coast ports in 1936 compared with 29,063 tons in 1935.

ROAD OIL

Increased construction of light types of highway resulted in an increase of 21 percent in sales of road oil by petroleum refineries in the United States—from 6,798,932 barrels in 1935 to 8,256,694 in 1936. However, if sales of road oil are considered with sales of cut-back asphalts, paving flux, and emulsified asphalts, there was a larger proportionate increase (30 percent) in total sales of liquid and semi-liquid asphalts for highway construction—from 12,316,545 barrels in 1935 to 16,052,833 in 1936.

Sales of road oil increased principally in California, northern Louisiana and Arkansas, the Gulf coast district of Texas, and the Oklahoma-Kansas-Missouri district. In California an increase of 831,308 barrels in sales of road oil was paralleled by an increase of 271,497 barrels in sales of cut-back asphalts. In the Oklahoma-Kansas-Missouri district an increase of 173,725 barrels in sales of road oil was exceeded by the increase of 382,729 barrels in sales of cut-back asphalts. In northern Louisiana and Arkansas an increase of 121,265 barrels in sales of road oil was accompanied by an increase of 40,766 barrels in sales of cut-back asphalts. No cut-backs were made in the Texas Gulf coast district, however, where sales of road oil increased 276,692 barrels from 1935 to 1936. On the other hand, a decrease of 49,223 barrels in sales of road oil by refineries of the Louisiana Gulf coast district was more than offset by an increase of 212,168 barrels in sales of cut-back asphalts, a decrease of 5,814 barrels in road-oil sales in the Indiana-Illinois-Kentucky district by an increase of 267,630 barrels in sales of cut-back asphalts, and a decrease of 6,406 barrels in road-oil sales in the Rocky Mountain district by an increase of 93,682 barrels in sales in cut-back asphalts.

Of the road oil sold in the United States in 1936, only 617,079 barrels valued at \$991,400 were made from foreign petroleum imported from Venezuela and Mexico. Of the road oil made from foreign crude, 89 percent was sold by refineries of the Atlantic seaboard in 1935 and 79 percent in 1936; the remainder was made in Gulf coast refineries of Louisiana and Texas.

Petroleum refineries in the United States reported the production of 7,397,868 barrels of road oil in 1936 compared with 6,030,491 barrels in 1935. The refinery output of road oil was augmented in 1936 by 1,096,583 barrels of other petroleum products, chiefly fuel oil, transferred to road-oil stocks compared with 1,399,656 barrels similarly transferred in 1935. Stocks of road oil and of transferred oils held at refineries increased from 739,605 barrels (revised figure) on December 31, 1935, to 851,035 on December 31, 1936. Consumption of road oil at refineries in their own operations, transfers, losses, and adjustments was 126,327 barrels in 1936 compared with 555,457 (revised figure) in 1935.

While the national average sales value of road oil at the refineries remained unchanged at \$1.26 in both 1935 and 1936, considerable local variations occurred from 1935 to 1936. In general, prices rose in the central United States—in the Indiana-Illinois-Kentucky district from \$1.25 per barrel in 1935 to \$1.31 in 1936, in the Oklahoma-Kansas-Missouri district from \$0.92 in 1935 to \$1.24 in 1936, in northern Louisiana and Arkansas from \$0.93 in 1935 to \$1.01 in 1936, and in the Gulf coast of Texas from \$1.53 in 1935 to \$1.65 in 1936. On the East coast sales values remained practically unchanged, averaging \$1.61 per barrel in 1935 and \$1.60 in 1936. On the other hand, the average sales value in the Rocky Mountain district fell from \$1.60 in 1935 to \$1.55 in 1936 and in California from \$1.10 in 1935 to \$1.01 in 1936.

Production of portland cement in the United States in 1936 increased to 112,396,000 barrels and shipments to 112,566,000 barrels valued at \$170,431,000, according to figures compiled from monthly reports of the Bureau of Mines. These quantities, which are above the 100-million barrel mark for the first time since 1931, represent a gain of 46 percent in production and 50 percent in shipments over 1935 but are still 36 percent less than those of the peak year, 1928, when 176,298,846 barrels were produced and 175,838,332 barrels shipped. In 1936 the industry operated at 42.7 percent of capacity, compared with only 28.6 percent in 1935, a low of 23.5 percent in 1933 and a high of 76.1 percent in 1927.

Extensive highway building, large Federal Public Works projects, and renewed activity in private construction all contributed to the increase in cement shipments. The degree of recovery in many other industries has been greater than that in cement manufacture, as is indicated by the fact that the Federal Reserve Board annual index for cement production in 1936 was 75, compared with 105 for all industries. Compared with the index of 55 for the construction industries, however, the showing of the cement industry is definitely encouraging, particularly in view of the consistent improvement month by month over the corresponding figures for 1935.

Prices were unchanged in 1936. The composite quotation of the Bureau of Labor Statistics remained at \$1.667 a barrel, and the average sales realization calculated from shipments reported to the Bureau of Mines was \$1.51 a barrel, as in 1935.

Shipments in 1936 include approximately 3,015,000 barrels of high-early-strength portland cement with an estimated mill value of \$5,769,000, compared with 2,109,000 barrels valued at \$4,032,000 in 1935.

The quantity of natural, masonry, and puzzolan cements produced gained 72 percent and the quantity sold, 65 percent. The value of sales of these varieties increased about 57 percent.

¹ Data for 1936 are preliminary; detailed statistics with final revisions will be released later.

The accompanying table of salient statistics presents the outstanding features of the cement industry in 1936 compared with previous years.

PORTLAND CEMENT

PRODUCTION, SHIPMENTS, AND STOCKS

The following tables show production, shipments, and stocks of portland cement by States and districts in 1934 and 1935 and summaries of monthly estimates of portland cement produced, shipped, and in stock at mills by districts in 1935 and 1936.

In the first table the term "active plant" is applied to a mill or group of mills situated at one place and operated by one company. If a company has establishments at different places its mill or group of mills at each place is counted as a plant. The districts are groups of States related geographically and commercially.

The tables giving data by months have been compiled from monthly reports of operators. Although the totals may differ slightly from those based on annual reports of producers, they reflect accurately the seasonal fluctuations in the industry.

Producers' stocks of portland cement reported on hand at the mills were less than 0.5 percent lower at the end of 1936 than at the end of 1935. The quantity of unground clinker on hand was more than 7 percent higher. The following table gives stocks on December 31 and the seasonal fluctuations in stocks from 1932 to 1936.

Producers' stocks of finished portland cement and clinker (unground cement) on hand at mills in the United States on Dec. 31 and monthly range, 1932-36

¹ Revised figures.

DOMESTIC CONSUMPTION

Apparent consumption (shipments plus imports minus exports) for a series of years is indicated in the table of salient statistics. The only available gauge of consumption by States is the record of shipments into States by manufacturers; it is therefore merely approximate. Cement manufactured and shipped to destinations within a State is of course added to that shipped from other States. Shipments into a State during any one year may not equal the consumption during that year, but over a series of years they give a fair average of consumption. The following table shows shipments into States in 1935 and 1936 and per-capita consumption in each State.

The official figures for exports of cement on page 1161 differ from those reported by manufacturers in the following table, because cement forwarded from mills and destined for foreign countries is reported by shippers as exported, whether or not it leaves the country during the calendar year, whereas the export figures of the Bureau of Foreign and Domestic Commerce record the cement that actually leaves the country during the period specified. Manufacturers report shipments to noncontiguous Territories of the United States as exports, while in official figures they are not so included. The exports recorded by the Bureau of Foreign and Domestic Commerce include all other hydraulic cement exported, whereas the figures supplied by producers relate to portland cement only.

The per-capita consumption indicated in the table falls short of the total apparent consumption by the quantity of imports, which affect certain States near the Canadian border and the seaboard.

PRICES

The average selling price of portland cement f. o. b. factories (excluding the price of containers and cash discounts), as reported to the Bureau of Mines, is given in the table of shipments by States and districts during 1934 and 1935 on page 1139. For certain States and districts white portland cement and other specially prepared types are included, thus the average prices are a little higher than if ordinary portland cement only were considered. Prices by States and districts are not yet available for 1936. The average factory price for the entire country in 1936 was \$1.51 a barrel, as in 1935. The average selling price f. o. b. factory of high-early-strength portland cement was \$1.91 a barrel, as in 1935. The sales value of natural, masonry, and puzzolan cements is given later in this chapter. The following table shows the average factory value of portland cement from 1932 to 1936.

Average factory value per barrel in bulk of portland cement in the United States, 1932-36

1932.....	\$1. 01'	1935.....	\$1. 51
1933.....	1. 33	1936.....	1. 51
1934.....	1. 54		

PLANT CAPACITY

In 1936 the cement industry operated at 42.7 percent of capacity compared with 28.6 percent in 1935. Figures for plant capacity are based on manufacturers' records supplemented by a few estimates. The following table shows the ratio of production to capacity by months during 1935 and 1936.

Ratio (percent) of finished portland cement produced to manufacturing capacity of the United States, 1935-36

RAW MATERIALS

The raw material used most extensively for cement manufacture in the United States comprises a mixture of high-calcium limestone and clay or shale. Next in importance is cement rock (argillaceous limestone) either alone or with the addition of high-calcium limestone. A mixture of marl and clay was used extensively prior to 1906, but in recent years most of the plants using marl have been abandoned or are supplied with other raw materials. Mixtures of blast-furnace slag and limestone are important raw materials for cement manufacture in several iron-smelting areas. The accompanying table shows trends in the use of the various raw materials from 1908 to 1935.

Production and percent of total output of portland cement in the United States, 1898-1914, 1926, 1929, 1933, and 1935, according to type of material used

Year	Type 1. Cement rock and pure limestone		Type 2. Limestone and and clay or shale		Type 3. Marl and clay		Type 4. Blast-furnace slag and limestone

¹ Includes output of 2 plants in 1926 and 3 plants in 1929, 1933, and 1935, using oyster shells and clay.

MANUFACTURING CONDITIONS

Plants.—In 1936 portland cement was manufactured and shipped from 149 plants, compared with 149 plants producing and 150 shipping in 1935. No new plants were built, and at least one old plant—the State cement plant at Chelsea, Mich., previously manned by prison labor—was dismantled. An old cement mill at Hartshorne, Okla., closed for 16 years, was scheduled for removal and rebuilding in 1937 at Houston, Tex., by the newly formed Gulf Portland Cement Co. The Lone Star Cement Corporation plant at Houston, Tex., was altered and enlarged. Control of another Texas plant, the Longhorn plant of the Republic Portland Cement Co. of San Antonio, changed hands as a result of stock purchase by Gus S. Wortham. The Riverside Cement Co., Oro Grande, Calif., resumed operation after several years of idleness. Early in the year the Marquette Cement Manufacturing Co. announced that it intended to transfer part of its plant capacity in northern Illinois to a southern location and was exploring rock deposits north of Vicksburg, Miss., which it had optioned. The Nazareth (Pa.) plant of the Lone Star Cement Corporation was modernized further during the summer. New silos were built for loading lake vessels by the Huron Portland Cement Co., and the Peerless Cement Corporation of Detroit began reconditioning machinery and buildings at its Port Huron, Mich., plant. Universal Atlas undertook rebuilding of its Leeds (Ala.) plant at an estimated cost of \$1,500,000. Calaveras Cement Co., San Andreas, Calif., completed various changes incident to producing white portland cement.

Millions of dollars are being spent by the industry on improvements. Universal-Atlas Cement Co. alone is reported to have a program calling for expenditure of \$11,000,000, of which \$3,000,000 has been released for rehabilitating its plants at Leeds, Ala., and Hudson, N. Y. Details of improvements made by many other companies are summarized in recent articles.²

Construction of a cement plant in Puerto Rico, financed by \$850,000 of Works Progress Administration funds, was begun in 1936. This is part of the Government plan to provide cheap cement for roads and home building on the island. Concrete buildings are desirable there, as frame structures are easily destroyed by hurricanes. Exports of hydraulic cement to Puerto Rico in 1936 amounted to 266,964 barrels valued at \$385,026.

Fuels.—According to monthly reports of producers the following quantities of fuel were consumed at portland-cement plants in the United States in 1936 in the production of 112,396,000 barrels of finished cement: Coal, 4,772,827 short tons; oil, 2,466,142 barrels; and natural gas 36,928,255,000 cubic feet.

The following table shows detailed data on fuels used in 1934 and 1935.

¹ Pit and Quarry, Cement Mills Spend Millions for Improvements as Shipments Soar to Highest Level in Five Years: Vol. 29, no. 1, 1936, pp. 63-67.
Nordberg, B., Cement Plants Add Latest Improvements: Rock Products, vol. 39, no. 10, 1936, pp. 60-65.

¹ Figures compiled from monthly estimates of producers.

² In addition to the coal shown for this group 2 plants in 1934 reported the use of petroleum coke with coal. The production figures for this group include the output of 1 plant which used coke-oven gas alone. In 1935, 1 plant reported the use of petroleum coke with coal and 1 plant the use of coke-oven gas with coal.

³ Average consumption of fuel per barrel of cement produced was as follows: 1934—coal, 129.0 pounds; oil, 0.2233 barrel; natural gas, 1,685 cubic feet. 1935—coal, 128.7 pounds; oil, 0.2097 barrel; natural gas, 1,621 cubic feet.

⁴ In addition to the coal and oil included for this group, 1 plant reported the use of petroleum coke with coal and oil.

⁵ In addition to the coal and natural gas included for this group 2 plants in 1934 reported the use of petroleum coke with coal and natural gas and 1 plant the use of oil and petroleum coke with coal and natural gas; in 1935, 3 plants reported the use of petroleum coke with coal and natural gas.

⁶ Includes 42,645 short tons of anthracite and 3,457,841 short tons of bituminous coal.

⁷ Includes 59,994 short tons of anthracite and 3,455,994 short tons of bituminous coal.

Natural gas is an important fuel for portland-cement manufacture in certain States. The following table shows the break-down in its use by States as far as permissible for 1934 and 1935.

Natural gas used at portland-cement plants in the United States, 1934-35, by States, in thousands of cubic feet ¹

State	1934	1935

Texas.....	4,513,105	5,258,614
Other States ²	18,150,431	17,192,310
	27,330,962	26,751,753

¹ Compiled from monthly estimates of producers.

² 1934: Arkansas, California, Colorado, Iowa, Missouri, Nebraska, Oklahoma, and South Dakota; 1935: Same States as in 1934, with the addition of Alabama and Louisiana.

Electric power.—The accompanying table shows the electric energy produced at cement plants and that purchased from power companies during 1934 and 1935. Such figures were first compiled in 1930, when 52.5 percent of the power was generated at the plants and 47.5 percent was purchased. The corresponding percentages for 1935, 52.4 and 47.6, show that conditions vary little from those in 1930.

Electrical energy used at portland-cement-producing plants, 1934-35, by processes, in kilowatt-hours

HIGH-EARLY-STRENGTH PORTLAND CEMENT

Manufacturing processes have been modified at many plants to produce portland cements that will attain high strength in a much shorter time than ordinary cements. Large quantities of such cements are now sold, particularly for projects in which the time factor is of great importance. Shipments in 1935 totaled 2,109,000 barrels valued at \$4,032,000. The following table shows shipments of such cements quarterly in 1936.

High-early-strength portland cement shipped from mills in the United States in 1936

Period	Number of shipping plants	Quantity (barrels)	Estimated mill value
First quarter.....	46	461,000	\$870,000
Second quarter.....	51	897,000	1,721,000
Third quarter.....	51	818,000	1,577,000
Fourth quarter.....	51	839,000	1,601,000
	51	3,015,000	5,769,000

NATURAL, MASONRY (NATURAL), AND PUZZOLAN CEMENTS

The term "masonry cement" is used here to designate certain cements made by grinding calcined calcareous rock (as are natural cements) and used largely in mortar for laying brick and stone, although other hydraulic cements also are suitable for masonry and are being manufactured for this purpose in increasing quantities.

Puzzolan cements are made of natural or artificial materials capable of forming hydraulic cements simply by admixture with lime and without the use of heat. Slags and various forms of volcanic ash are the principal puzzolanic materials. Such cements find special uses be-

cause of their high resistance to sulphate and alkali waters. The following table shows production of natural and puzzolan cements in recent years.

Natural, masonry (natural), and puzzolan cements produced, shipped, and in stock at mills in the United States, 1932-36

Year	Production		Shipments		Stock (Dec. 31)
	Active plants	Barrels (376 pounds)	Barrels (376 pounds)	Value	Barrels (376 pounds)
1932.....	15	456, 785	524, 844	\$696, 474	150, 164

TECHNOLOGY

Improved grinding, better proportioning of raw materials, storage of mixed clinker, more attention to what happens inside the kiln during firing, clinker cooling, preheating of combustion air, and dust collection are all receiving careful attention in the cement industry, judging from the record of plant improvements during 1936. Increased flexibility of operations is another goal, and more companies are giving thought to the production of special cements.

Definition.—Recognizing the importance of high-early-strength portland cement, Committee C-1 of the American Society for Testing Materials has proposed the following definition:

Portland cement is the product obtained by pulverizing clinker consisting essentially of calcium silicates, to which no additions have been made subsequent to calcination other than water and/or untreated calcium sulphate except that additions not to exceed 1 percent of other materials may be added, provided such materials have been shown not to be harmful by tests prescribed and carried out by Committee C-1.

Byproducts.—The Oklahoma Portland Cement Co., Ada, Okla., is shipping 10 to 15 tons of solid carbon dioxide a day as a byproduct.

Kiln insulation.—By investing \$3,990 for insulation in its Clinchfield (Ga.) plant, the Pennsylvania-Dixie Cement Corporation has saved \$24,030 in coal costs in 6 years.³

Basset process.—The first actual installation of a rotary kiln for the simultaneous production of iron and portland cement is at the cement plant of the Compania Asland, Moncada, Spain. The raw materials are iron ore, limestone, and coke breeze or anthracite. The kiln is 45 meters long and 2.8 meters in diameter. After the usual reactions are completed in the cement kiln at 1,400° C., corresponding to the sintering-zone temperature in ordinary portland-cement manufacture, the material passes on to the hottest zone where it reaches 1,500° C.; this melts the iron, part of which flows out through an opening in the shell and part of which is removed subsequently by passing the cooled clinker over a magnetic separator. The cement so produced meets the Spanish standard specifications for portland cement.⁴

³ Rock Products, Rotary Kiln Insulation Pays: Vol. 39, no. 8, August 1936, p. 47.

⁴ Pit and Quarry, Rotary Kiln Produces Both Cement and Iron: Vol. 28, no. 12, June 1936, p. 71.

Seasoning.—According to Roller⁵ portland cement absorbs water vapor from an atmosphere of steam at temperatures above the dew point; the rate is rapid during the first few minutes of exposure and then declines. For steam-air mixtures the quantity of moisture absorbed depends solely on the ratio of absolute temperature of exposure to that of the dew point. Progressive absorption up to a certain limit retards the set and reduces the proportion of mixing water required for normal consistency. When corrections were made to allow for the effect of gypsum admixture, cements that had absorbed least moisture had the lowest strengths. Cements that had absorbed most moisture also had the greatest resistance to the action of carbon dioxide at room temperature. The advantages of controlled sintering at elevated temperatures are indicated.

Special cements.—The construction of enormous dams during recent years has led to intensive research on the best types of cement for mass concrete work. The first major efforts were directed toward a reduction in the heat of hydration by development of a "low heat" type. This was accomplished by decreasing the cement compounds responsible for most of the generation of heat, namely, the tricalcium silicate and tricalcium aluminate. Such reduction necessitated an increase in the percentages of dicalcium silicate and tetracalcium aluminoferrite, which resulted in a much slower development of strength. The slow attainment of strength in these low-heat cements is accelerated somewhat by fine grinding. This type of cement was used in the Morris Dam in California and the Boulder Dam on the Colorado River.

Because of the slow gain in strength of low-heat cement a compromise product known as the modified or moderate-heat type was developed. It reverted to standard portland cement in its content of tricalcium and dicalcium silicates but retained the low percentage of tricalcium aluminate used in low-heat cement. This moderate-heat type with very fine grinding develops strength at about the same rate as standard portland cement, attains higher ultimate strength in mass concrete work, and generates 10 percent less heat than standard cement, whereas the low-heat type develops 27 percent less heat. Moderate-heat cement was used in the Norris Dam in Tennessee and is being used in the Grand Coulee Dam in Washington.

FOREIGN TRADE⁶

Imports.—The figures in the two following tables cover imports of hydraulic cements of all kinds. The values assigned to imports, supposed to represent values in the foreign countries from which the materials are exported, include the cost of containers. The first table shows total imports for a series of years, and the second, imports by countries and by districts of entry in 1935 and 1936.

Hydraulic cement imported for consumption in the United States, 1932-36

Exports.—Although the United States is the major cement-producing country of the world, its export trade is small. The following table shows exports for a series of years and their relation to total shipments. Exports in 1936 were less than one-third of 1 percent of the total quantity shipped from domestic plants.

WORLD PRODUCTION

The following table, copied from the Statistical Year Book of the League of Nations, 1935-36,⁷ gives data on the cement output of the world from 1931 to 1935. The figures are in thousands of metric tons (1 metric ton equals 2,204.6 pounds).

For 1934, the latest year for which reasonably complete data are available, the principal cement-producing countries were, in order of importance: United States, Germany, United Kingdom, Japan, France, Italy, and U. S. S. R. (Russia). In that year the United States produced about 23 percent of the estimated output of the world.

⁷ League of Nations, Statistical Year Book, 1935-36: Geneva, 1936, p. 129.

General conditions	1165	Dimension stone—Continued.	
Dimension stone	1168	Foreign trade	1190
Status of industry	1168	Imports	1190
Salient statistics	1170	Exports	1193
Granite	1171	Crushed and broken stone	1193
Trap rock	1175	General conditions	1193
Marble	1177	Salient statistics	1194
Limestone	1178	Production by kinds	1195
Sandstone	1184	Markets	1197
Miscellaneous stone	1187	Commercial and noncommercial operations	1198
Trends in use of building stone	1189	Methods of transportation	1199
New developments	1190		

The stone industries experienced decided improvement in 1936. Dimension-stone sales gained 27 percent in quantity and 43 percent in value over 1935, while crushed-stone sales gained 48 percent in both quantity and value. The industry had reached such a low level of activity in 1935 that even with these large gains the sales value in 1936 was still only 64 percent of that attained in 1929.

Stone producers depend for their prosperity to an unusual degree on the volume of building and highway construction; therefore, they suffered greatly since 1929, during which period building activity has been sluggish. All branches of the industry shared in the recession, but some have recovered more rapidly than others.

The decline in the building-stone industry was sharper and more persistent than for most building materials. An increase in the value of construction contracts awarded, from a low of 25 percent of the 1923–25 average in 1933 to 37 percent in 1935 and 55 percent in 1936, has not brought about a corresponding recovery in the use of stone. Building-stone sales, in fact, declined moderately in quantity and very greatly in value from 1933 to 1935, but gained substantially in 1936. The delay in recovery may be attributed, at least in part, to an endeavor to keep building costs low, with consequent use of lower priced building materials at the expense of stone. Furthermore, Government building of large stone structures has declined, so that any gain in construction was chiefly in the field of residential building, in which only small quantities of stone are employed.

Crushed-stone sales recovered somewhat in 1934 and dropped again in 1935, but advanced to a higher level in 1936. The most substantial gains since 1933 have been made by Government agencies (noncommercial production). Therefore, the stone-producing industries have not experienced as great a recovery as the figures for total production would indicate.

The tables in this report give the quantities sold or used by producers and the values f. o. b. quarries and mills insofar as these figures

¹ Data for 1936 are preliminary; detailed statistics with final revisions will be released later.

are obtainable. Stone quarried and used by the producer is considered as sold and is included in the statistics on sales. The figures, however, do not include stone made into abrasives (such as grindstones) or that used in the manufacture of lime and cement. These amounts are reported in terms of finished products in the Abrasive Materials, Lime, and Cement chapters of this volume. The following table shows production of stone by kinds for the past 5 years.

Stone sold or used by producers in the United States, 1932-36, by kinds

¹ Subject to revision.

² Includes mica schist, conglomerate, argillite, various light-colored volcanic rocks, serpentine not used as marble, soapstone sold as dimension stone, and such other stone as cannot properly be classed in any main group.

The following table of production by uses indicates a substantial gain in all branches of the dimension-stone industries in 1936, except that for paving blocks, which fell about 27 percent in quantity below the level of 1935. Sales of crushed and broken stone show large gains. Sales of riprap more than doubled, principally because of the demand for such stone in the construction of large dams in the far West. Furnace- and refractory-stone sales advanced in consonance with the great activity in steel plants.

² To avoid disclosing confidential information, certain State totals are slightly incomplete, the figures not included being combined under "Undistributed".

³ Includes various portable plants operated noncommercially but combined as one plant.

DIMENSION STONE

The years 1934 and 1935 were about the worst in the history of the dimension-stone industries, but definite improvement took place in 1936. The recovery was shared by all the major varieties of stone. Total sales exceeded 2,000,000 tons valued at about \$26,000,000 compared with about 1,560,000 tons valued at nearly \$18,000,000 in 1935.

The principal kinds of dimension stone are granite, marble, limestone, sandstone, basalt, and slate. Although the slate industry is reviewed in a separate chapter, slate statistics are included in the table of salient statistics in this chapter to show total sales of dimension stone.

Dimension-stone producers may be divided into three main groups on the basis of plant operation; the first group includes operators who quarry stone and sell it as rough blocks or slabs; the second group quarries and manufactures stone into finished products; and the third buys sawed or rough stock and manufactures products but does not operate quarries.

The Bureau of Mines statistical canvass covers the first and second groups, but as the third group includes manufacturers rather than producers it is canvassed by the Bureau of the Census. Bureau of Mines statistics are compiled from reports of tonnages and values of original sales; it is evident, therefore, that they include some material sold as rough blocks and some sold as finished products.

The following table of salient statistics includes final figures for sales of dimension stone in 1935, preliminary figures for 1936, and the percentage of change from 1935 for each kind of stone by principal products.

Dimension stone sold or used by producers in the United States, 1935-36, by kinds and uses

¹ Subject to revision.

² Includes soapstone, mica schist, volcanic rocks, argillite, and other varieties that cannot properly be classed in any main group.

³ Details of production, by uses, are given in the chapter on Slate in Minerals Yearbook, 1937.

⁴ Revised figures.

Granite.—The granite industry gained in all branches except in paving-block manufacture. Building stone increased greatly in value although the quantity sold was much smaller. This was because sales of rough construction stone were reduced while sales of the higher-priced cut stone increased 50 percent. Demand for monumental stone and curbing increased encouragingly.

Sales of crushed and broken stone are included in this table and in corresponding tables for other kinds of stone, but these classes are discussed later in this chapter.

Granite sold or used by producers in the United States, 1935-36, by uses

The district surrounding Barre, Vt., is the most productive area in the United States for memorial granite. Therefore, production figures as given in the following table are interesting.

Monumental granite sold by the quarrymen in the Barre district, Vermont, 1932-36 ¹

Year	Cubic feet	Value	Year	Cubic feet	Value
1932.....	618,890	\$1,549,113	1935.....	676,820	\$1,844,006
1933.....	563,570	1,405,270	1936 ¹	797,000	2,187,000
1934.....	709,820	1,878,644			

¹ Barre granite is sold also for construction, paving blocks, and crushed stone.

² Subject to revision.

Basalt and related rocks (trap rock).—Basalt and related rocks are not used extensively for building purposes, but sales in 1936 were more than three times as great as in 1935. The following tables show production by uses in 1935 and 1936 and by States in 1935.

Basalt and related rocks (trap rock) sold or used by producers in the United States, 1935-36, by uses

Marble.—Sales of marble were more than twice as great in 1936 as in 1935, and the sales value per cubic foot increased from \$4.63 to \$4.82. Sales of monumental marble increased moderately.

Serpentine ¹ (verde antique) sold by producers in the United States in 1935, by uses

Use	Quantity	Value
Building and ornamental stone.....cubic feet..	7, 990	\$87, 657
Rough construction, crushed, etc.....short tons..	162, 930	195, 073

¹ Serpentine sold from dimension-stone quarries is included in the figures for marble; serpentine sold for road work and other low-grade material is included in the figures for "miscellaneous" stone.

Limestone.—Sales of limestone for rough construction increased a little in 1936, while sales of cut stone increased greatly. More limestone is being used in private building. The following tables show sales by principal uses in 1935 and 1936 and more detailed data on the industry by States in 1935.

Sandstone.—Sales of sandstone for rough construction in 1936 increased 77 percent in quantity and 124 percent in value over those of 1935. Prices sagged greatly in 1935 but recovered encouragingly in 1936. Ohio is the leading producer. The variety known as blue-stone that is characteristic of certain districts in New York and Pennsylvania is covered in one of the tables that follow.

Sandstone sold or used by producers in the United States, 1935-36, by uses

1 Included under "Undistributed."

2 Includes various portable plants operated noncommercially but combined as 1 plant.

Trends in the use of building stone.—Dimension stone depends for its markets primarily on the building industries, principally on buildings of the nonresidential classes. Figures 82 and 83 show graphically the trends in sales of the principal building stones in relation to total building and nonresidential building from 1927 to 1936. The upturn in building in 1936 is reflected in the increasing activity in sales of stone. All classes of stone show substantial gains in sales, but marble sales increased most.

FIGURE 82.—Sales of limestone and sandstone, compared with total building and nonresidential building, 1927-36. To facilitate comparison, unlike units have been reduced to percentages of the 1927 value. Stone figures are from the Bureau of Mines and include rough and dressed stone; contracts are from F. W. Dodge Corporation.

FIGURE 83.—Sales of building marble and granite, compared with total building and nonresidential building, 1927-36. To facilitate comparison, unlike units have been reduced to percentages of the 1927 value. Stone figures are from the Bureau of Mines and include both rough and dressed stone; contracts are from F. W. Dodge Corporation.

Trends in sales of memorial stone.—Sales of memorial granite increased 23 percent and of marble 17 percent in quantity compared with 1935. Prices of both kinds were a little lower than in 1935.

NEW DEVELOPMENTS

Recent changes in tariff rates on granite may influence foreign trade. The tariff on unmanufactured granite—25 cents per cubic foot under the Tariff Act of 1930—was reduced to 20 cents under the reciprocal treaty with Sweden and later to 12½ percent under agreement with Finland. The present rate is equivalent to about 10 percent ad valorem. The duty on manufactured granite which was 60 percent under the Tariff Act of 1930 was reduced to 30 percent under the Finland treaty.

According to an item in the Monumental and Architectural Stone Journal (London), the granite industries of Aberdeen, Scotland, have developed a new and better process for polishing granite, but no details are available.

A new building unit known as "insulated natural stone" is now manufactured in Milwaukee, Wis. Two-inch slabs of Briar Hill (Ohio) sandstone in random lengths and in heights of 2¼, 5, and 7¼ inches are set in the center of a mold, and light weight concrete is filled in on both sides. The sandstone slab is then split in the center, producing two building units, each consisting of 3 inches of light weight concrete faced with 1 inch of stone. The bond between the concrete and stone is firm.

A summary of recent accomplishments with the wire saw in slate, limestone, and sandstone quarries has recently been published.²

FOREIGN TRADE¹

Imports.—Foreign trade in stone is confined chiefly to dimension stone. Imports in 1936 increased 20 percent in value over 1935. The following tables show the value of imports for a 5-year period and the quantities and values by kinds imported in 1936.

Value of stone imported for consumption in the United States, 1932-36

1932.....	\$766, 706	1935.....	\$556, 584
1933.....	536, 643	1936.....	665, 983
1934.....	413, 301		

Stone imported for consumption in the United States in 1936, by classes

		380, 632	Rough (monumental or building stone).....cubic feet..	2, 229	3, 688
Granite: Dressed ¹cubic feet..	16, 227	67, 210	Rough (other).....		7, 050
Rough.....do.....	43, 069	63, 627			16, 209
	59, 316	130, 837	Grand total.....		665, 983

¹ Also paving blocks valued at \$83.

The following table gives imports by countries in 1936. The principal gains were in imports of marble and travertine from Italy. Onyx marble imports from Mexico more than doubled, but imports of this variety from Argentina were smaller in 1936 than in 1935. Granite imports were about the same in both years.

Exports.—Exports of stone, with which are included cement blocks and other cement manufactures, increased about 2 percent in value in 1936 compared with 1935. The quantity shipped to Cuba shows the most marked increase, but the total export trade is relatively unimportant.

Stone¹ exported from the United States, 1932-36, by classes

CRUSHED AND BROKEN STONE

Sales of crushed and broken stone in 1936 increased more than 47 percent over 1935. The average price remained the same. All branches of the industry, except stone for glass factories, shared in the advance. The most notable gains were in concrete and road metal, metallurgical stone, refractory stone, agricultural limestone, and riprap.

The following table of salient statistics shows the quantity and value of crushed and broken stone sold during 1935 and 1936 by uses. Detailed data on asphaltic stone and slate granules and flour are given in the chapters of this volume on Asphalt and Slate.

² Included under "Undistributed."

Production by kinds.—The following table shows the quantity of each kind of stone employed as aggregate, road stone, or ballast in 1935 and 1936. Of the 1936 totals, about 64 percent was limestone, 13 percent trap rock, 9 percent granite, 5 percent sandstone, and 9 percent miscellaneous stone. The average values per ton at the quarry also are shown in the table.

Concrete and road metal and railroad ballast sold or used by producers in the United States, 1935-36, by kinds

Limestone is the most important of all stones used in crushed or broken form because it is regarded as an essential constituent of many products and necessary to the success of many chemical and manufacturing processes. The table on page 1178 shows the principal uses, and those designated as "Other uses" are further subdivided in the following table:

² Bureau of Mines not at liberty to publish figures.

Limestone is used not only in its natural state but is employed extensively as raw material for making cement and lime. These commodities are discussed in separate chapters, but the amount of limestone so used, together with that employed raw, is indicated in the following table. The tonnage of limestone employed for all purposes was nearly 44 percent greater in 1936 than in 1935.

Limestone used for all purposes in the United States, 1935-36, in short tons

² Value reported as cement in the chapter on Cement.

³ Value reported as lime in the chapter on Lime.

Markets.—Sales of crushed stone for major uses bear a definite relation to the volume of concrete pavement constructed and to sales of portland cement, because stone is used extensively as concrete aggregate. Figure 84 shows this relationship from 1927 to 1936. Highway building, public works projects, and construction in general furnish important markets for crushed stone.

Stone is used extensively in metallurgy. Limestone is employed as a flux in blast furnaces and other metallurgical plants for the purpose of forming a slag to carry off the impurities in ores and metals. Dolomite, ganister, and mica schist are employed as refractories. Therefore, a close relationship exists between sales of stone for these uses and activity in the iron and steel industries as indicated in figure 85.

FIGURE 84.—Sales of concrete and road metal (crushed stone) compared with total construction, portland-cement shipments, and contracts for concrete pavements, 1927-36. Data are plotted as index numbers with the 1923-25 average as 100. Figures on cement and stone compiled by the Bureau of Mines, on concrete pavements by the Portland Cement Association, and on construction contracts by the F. W. Dodge Corporation.

FIGURE 85.—Sales of fluxing stone and refractory stone compared with production of steel ingots and pig iron, 1927-36. All data are plotted as index numbers, with the 1923-25 average as 100. Statistics of steel-ingot and pig-iron production compiled by American Iron and Steel Institute.

Commercial and noncommercial operations.—During recent years Government agencies of various kinds have become important producers of crushed stone. Because of the general interest in such trends, the following table is presented. It may be noted that non-commercial production increased from about 11 percent of the total in 1931 to more than 30 percent in 1935. Statistics for 1936 are not yet available.

*Crushed stone sold or used by commercial and noncommercial operators in the United States, 1931-35*¹

Figures for "Noncommercial operations" represent tonnages reported by States, counties, municipalities, and other Government agencies, produced either by themselves or by contractors expressly for their consumption, often with publicly owned equipment; they do not include purchases from commercial producers. Figures for "Commercial operations" represent tonnages reported by all other producers]

The slate industry, which suffered a severe decline during recent years, has made a remarkable recovery. The value of sales at the low point of the depression in 1933 was only 21 percent of that in the peak year, 1925. A slow upturn in 1934 was followed by a large increase in 1935, and in 1936 the quantity of slate sold was 37 percent and the value 50 percent greater than in 1935. The value of sales in 1936 was more than twice as great as in 1933. Sales of slate in 1936 totaled 452,400 tons valued at \$5,485,208, compared with 330,200 tons valued at \$3,649,515 in 1935.

Roofing slate sold in 1936 totaled 366,130 squares valued at \$2,607,402, a gain of 65 percent in quantity and 79 percent in value over 1935. The average value per square in 1936 was \$7.12, whereas in 1935 it was \$6.57. The output of the Pennsylvania district was 235,780 squares valued at \$1,603,734 in 1936, a gain of 63 percent in quantity and 82 percent in value over 1935. In the New York-Vermont district 94,760 squares valued at \$697,505 were sold, a gain of 63 percent in quantity and 70 percent in value over 1935. In Virginia the gain over 1935 was 92 percent in both quantity and value. Maine showed a substantial gain.

Sales of millstock in 1936 were nearly 40 percent greater than in 1935. Millstock includes all slate used for structural and sanitary purposes, electrical products, blackboards, bulletin boards, school slates, billiard-table tops, vaults, covers, and similar products. A gain in total building construction from 37 percent of the 1923-25 average in 1935 to 55 percent in 1936 led to gains of 44 percent in quantity and 32 percent in value of sales of structural slate. The high level of electrical output in 1935 doubtless accounted for the gain of 30 percent in quantity and 29 percent in value of sales of electrical slate. Production of school slates, which is relatively small, was the only branch of the industry to show a decline in 1936. Public Works Administration funds have made possible the erection of many new schools; therefore the gain of 81 percent in quantity and 66 percent in

value of blackboards sold was to be expected. Sales of vaults and covers show small gains, but slate for flagging, cross walks, and stepping stones, which are becoming increasingly popular, gained more than 50 percent.

The following table giving the principal statistical data for the slate industry during 1935 and 1936 is arranged to permit ready comparison of the 2 years. Granules and flour, which have little connection with the slate industry, appear in the table because they are manufactured from slate, although much of the material so used is derived from deposits that could not be utilized for ordinary slate products. Slate granules and flour are properly crushed-stone products and therefore are included also with other kinds of granules in the chapter of this volume on Stone.

Salient statistics of the slate industry in the United States, 1935-36

³ Includes walkways, stepping stones, and miscellaneous slate.

⁴ Figures not available: included in exports of stone.

⁵ Collected by the Bureau of Mines from shippers.

SALES

Dimension slate.—The following table shows for recent years sales of dimension slate; that is, all slate sold in blocks or slabs cut to specified sizes and shapes. Such a classification excludes granules and flour.

Slate (other than granules and flour) sold by producers in the United States, 1922-31 (average) and 1932-36

Year	Roofing			Millstock		Other ¹		Total	
	Squares	Ap- prox- imate equiv- alent short tons	Value	Ap- prox- imate short tons	Value	Ap- prox- imate short tons	Value	Ap- prox- imate short tons	Value
1922-31 (average).....	444,845	157,751	\$4,444,978	50,006	\$3,454,329	7,485	\$87,816	215,242	\$7,987,123

¹ Includes flagstones, walkways, stepping stones, and miscellaneous slate.

² Revised figures.

FIGURE 86.—Sales of slate compared with residential building and total building, 1927-36. Statistics of slate compiled by the Bureau of Mines and those for building by the F. W. Dodge Corporation.

Figure 86 compares sales of slate, except granules and flour, from 1927 to 1936 with contracts awarded for residential building and total building during the same period. The figure illustrates the close relation between activity in the slate and construction industries, particularly for the years since 1929. In 1936, slate sales gained almost as rapidly as residential building.

Granules and flour.—The following table shows granules and flour sold by producers from 1932 to 1936:

Crushed slate (granules and flour) sold by producers in the United States, 1932-36

Year	Granules		Flour		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1932	174, 140	\$1, 058, 713	35, 610	\$139, 103	209, 750	\$1, 197, 816
1933	146, 880	1, 024, 917	39, 500	155, 405	186, 380	1, 180, 322
1934	123, 290	902, 078	42, 870	164, 022	166, 160	1, 066, 100
1935 ¹	166, 520	1, 112, 081	59, 990	196, 264	226, 510	1, 308, 345
1936	202, 730	1, 372, 095	86, 920	274, 685	289, 650	1, 646, 780

¹ Revised figures.

Trends in roofing slate.—Residential building is the principal market for roofing slate. There are no statistics available of the roof area of new residential construction, but the F. W. Dodge Corporation publishes data regularly on the floor space represented by contracts awarded. It may be assumed that roof area bears a fairly definite relationship to floor space; therefore the latter may be regarded as a rough index of the area that must be covered with roofing.

FIGURE 87.—Sales of roofing slate compared with residential floor space, 1927-36. Statistics for slate compiled by the Bureau of Mines and those for floor space by the F. W. Dodge Corporation.

Figure 87 compares sales of roofing slate in squares with residential floor space of new construction from 1927 to 1936. Slate is used for reroofing as well as in new construction, but no figures are available as to the proportion of each. New construction is, however, the principal market, and the chart indicates that slate did not suffer as severe a decline as residential building during the depression. The rapid gain in sales of slate during 1935 and 1936 shows that, compared with past years, slate is maintaining a favorable position in competition with other roofing materials, although it covers only a small percentage of all roofs.

PRICES

Roofing-slate prices, as indicated by sales f. o. b. quarry or mill reported by producers to the Bureau of Mines, gained 55 cents a square—from \$6.57 a square in 1935 to \$7.12 in 1936. The principal advance was in the Pennsylvania district, where the average sale price was 71 cents a square higher than in 1935; in the Vermont-New York district the increase was 29 cents a square.

Millstock prices were virtually the same in 1936 as in 1935. Electrical slate, structural slate, and blackboards sold at slightly lower and school slates at slightly higher prices.

FIGURE 88.—Prices of slate compared with commodity prices of building materials in general, 1927-36. Statistics for slate compiled by the Bureau of Mines; commodity prices by the Bureau of Labor Statistics.

Trends in recent years.—Figure 88 shows graphically the trend of slate prices during the past 10 years compared with prices of building materials in general. Slate prices declined sharply between 1929 and 1932, but not more precipitously than those of other building materials. Since 1932 prices of building materials have recovered greatly; but, as shown on the chart, slate prices have remained at abnormally low levels. Roofing-slate prices recovered somewhat in 1934 but declined again in 1935. However, the substantial upturn in 1936 promises a more prosperous era.

REVIEW BY DISTRICTS

The following table shows sales of slate in 1935 and 1936 by States and uses:

Slate sold by producers in the United States, 1935-36, by States and uses

¹ Flagging and similar products, granules, and flour.² Revised figures.³ Included under "Undistributed".⁴ A small amount of millstock included under "Other".⁵ For detailed table for Pennsylvania, see p. 1207.⁶ Includes output of States entered as (³) above.

Maine.—Electrical slate, which is the chief product of the Maine quarries, gained about 31 percent in quantity and 29 percent in value in 1936 compared with 1935. Roofing slate, which is of minor importance, made a substantial gain.

New York-Vermont.—The deposits of New York and Vermont furnish all the colored roofing slate now sold in the United States. Granules and flour, the chief products of the New York quarries, increased 18 percent in value of sales in 1936 compared with 1935. Green, mottled, and purple slates are produced in large quantities in the Vermont quarries. Sales of roofing slate in this State increased 65 percent in quantity and 72 percent in value in 1936 over 1935. Sales of millstock (structural, sanitary, and electrical slate), which is an important product in Vermont, were about one-third greater in 1936 than in 1935. The total value of sales of slate products in Vermont gained nearly 53 percent in 1936.

Peach Bottom district.—The Peach Bottom district situated near Delta, Pa., and Cardiff, Md., is an important source of slate granules and flour. A high-grade, blue-black roofing slate was produced in considerable quantities during past years, but recently production has been very small. In 1936 The Funkhouser Co., a large producer of granules, began production of roofing slate near Delta.

Lehigh district.—The Lehigh district of Pennsylvania furnished roofing, structural, sanitary, and electrical slate, blackboards, school

slates, flagging, granules, and slate flour. It is the most productive slate district in the United States. The following table shows sales in this district in 1935 and 1936 and includes the output of granules and flour in Berks and York Counties.

Slate sold by producers in Pennsylvania, 1935-36, by counties and uses

¹ Exclusive of billiard-table material, value for which is included under "Other."

² Includes slate for grave covers and vaults.

³ Includes billiard-table material, as follows: 1935, 4,720 square feet valued at \$1,855; 1936, 7,680 square feet valued at \$3,363.

⁴ Revised figures.

⁵ Berks and York Counties produced roofing granules and flour only.

Both hard and soft slate are produced. The former is used almost exclusively for roofing and the latter for both roofing and millstock.

The output of all products of the industry in this district showed decisive gains except that of school slates, which decreased 30 percent in quantity and 25 percent in value compared with 1935. Sales of roofing slate increased 63 percent in quantity and 82 percent in value; electrical slate, 17 percent in quantity and 23 percent in value; structural and sanitary slate, 32 percent in quantity and 28 percent in value; and blackboards, 81 percent in quantity and 66 percent in value. Granules and flour sales gained 33 percent in value. The value of total sales of slate products advanced 61 percent in 1936 over 1935.

Virginia.—Principal production is in Buckingham County, which produces roofing slate almost exclusively. Sales of roofing slate in

1936 increased about 92 percent in both quantity and value compared with 1935.

Other districts.—Georgia and Tennessee reported production of granules and a small quantity of roofing slate. The output in California consists chiefly of granules.

NEW DEVELOPMENTS

It was reported in June 1936 that a slate quarry at Madoc, Ontario, Canada, which was operated about 50 years ago, was about to be reopened.

Tests conducted in England indicate that certain slates when calcined will expand greatly to give a product that serves well as a lightweight aggregate for concrete. This suggests a possible profitable utilization of waste slate in the United States.

FOREIGN TRADE ¹

Imports.—The value of slate imported for consumption in the United States in 1936 was slightly higher than in 1935 but only about 6 percent of the value of imports in 1929. The following table shows value of imports from 1931 to 1936.

Value of slate imported for consumption in the United States, 1931-36

1931-----	\$46, 581	1934----	\$12, 639
1932-----	17, 317	1935----	5, 497
1933-----	9, 688	1936----	5, 548

The following table shows the value of imports in 1935 and 1936 by countries.

Value of slate (manufactured) imported into the United States, 1935-36, by countries

Country	1935	1936	Country	1935	1936
Canada-----	\$2, 033	\$1, 074	Japan-----	\$360	\$195

Czechoslovakia-----	2, 317	1, 904			
Hong Kong-----	83	21		5, 497	5, 548
Italy-----	667	2, 083			

Exports.—The following table shows exports of roofing slate from 1932 to 1936. Exports of roofing slate were included with exports of stone in 1936, therefore a separate figure cannot be given.

Roofing slate exported from the United States, 1932-36

Year	Number of squares	Value	Year	Number of squares	Value
1932-----	1, 792	\$12, 215	1935-----	1, 390	\$11, 175
1933-----	1, 155	7, 244	1936-----	(¹)	(¹)
1934-----	1, 128	9, 851			

¹ Figures not available; included in exports of stone.

¹ Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

The following table shows exports of slate other than roofing slate from 1934 to 1936. Exports of all products except school slates show large increases in 1936 compared with 1935. School slates declined a little in quantity but increased in value. The value of all slate exports was 84 percent higher in 1936 than in 1935.

Slate other than roofing exported from the United States, 1934-36, by uses ¹

Use	1934		1935		1936	
	Quantity	Value	Quantity	Value	Quantity	Value

Production.....	1213	Prices.....	1222
Noncommercial.....	1218	Markets.....	1223
Method of transport.....	1220	New developments.....	1223
Preparation.....	1220	Foreign trade.....	1224

Greater activity in building and highway construction in 1936 resulted in increased business for commercial sand and gravel producers, compared with 1935. With the continuation of extensive secondary road programs in many States, partly with work-relief funds, the output of noncommercial operations likewise increased. Available data on consuming markets for sand and gravel and incomplete returns from producers indicate that the total output of commercial and noncommercial plants in 1936 was 172,660,000 short tons valued at \$88,747,000. This apparent increase of 39 percent in tonnage and 43 percent in value from 1935 continued the upswing that began in 1934 following a sharp decline from 1929 to 1933. (See fig. 89.)

FIGURE 89.—Principal trends in the sand and gravel industry, 1905-36.

Sales of sand and gravel for all important uses increased in 1936 compared with 1935. Building sand and gravel sales, in particular, were much higher than in 1935, and sales for paving and railroad ballast also advanced sharply. The demand for glass, molding, and other industrial sands reflected the marked acceleration in general business conditions, the range of increase being 1 to 34 percent. The total output of commercial sand and gravel operations in 1936 was 119,660,000

¹ Data for 1936 are preliminary; detailed statistics with final revisions will be released later.

short tons compared with 84,607,471 tons in 1935, an increase of 41 percent.

Partial returns from States, counties, municipalities, and other local government agencies indicate that the production of sand and gravel at noncommercial plants increased to about 53,000,000 tons in 1936, 35 percent above 1935. Prices were virtually unchanged from 1935.

Salient statistics of the sand and gravel industry in 1935 and preliminary figures for 1936 are summarized in the following table:

Sand and gravel sold or used by producers in the United States, 1935-36, by commercial and noncommercial operations and by uses

¹ Subject to revision.

² Includes some sand used for fills and similar purposes. The quantity of sand reported as used exclusively for railroad ballast in 1935 was 870,600 tons valued at \$237,059; break-down for 1936 not available. The figures include sand produced by railroads for their own use as follows—1935: Ballast, 173,408 tons valued at \$21,003, and fills and similar purposes, 126,889 tons valued at \$19,863; 1936: Break-down not available.

³ Includes some gravel used for fills and similar purposes. The quantity of gravel reported as used exclusively for railroad ballast in 1935 was 7,272,186 tons valued at \$2,107,184; break-down for 1936 not available. The figures include gravel produced by railroads for their own use as follows—1935: Ballast, 3,280,094 tons valued at \$471,108, and fills and similar purposes, 274,303 tons valued at \$36,091; 1936: Break-down not available.

⁴ By States, counties, municipalities and other government agencies, directly or under lease.

⁵ Not available.

PRODUCTION

Although preliminary figures are available to indicate the approximate output of the sand and gravel industry in 1936, complete details by States and by uses could not be compiled in time for inclusion in the current volume of the Minerals Yearbook. These detailed data for 1936, however, will be released in temporary form as soon as the canvass is completed and, to maintain the historical continuity of the statistics in the permanent record, will be included in the next volume of the Yearbook. Similarly, complete details for 1935 are given in the following tables:

Sand and gravel sold or used by producers in the United States, 1931-36

Year	Sand		Gravel (including railroad ballast)		Total

1 Includes noncommercial production.

2 Included under "Undistributed."

3 Includes items entered as "2."

4 Includes some sand used for fills and similar purposes. The quantity of sand reported as used exclusively for ballast was 870,600 tons valued at \$237,059. The figures include sand produced by railroads for their own use as follows: Ballast, 173,408 tons valued at \$21,003; fills and similar purposes, 126,889 tons valued at \$19,863.

5 Includes some gravel used for fills and similar purposes. The quantity of gravel reported as used exclusively for ballast was 7,272,186 tons valued at \$2,107,184. The figures include gravel produced by railroads for their own use as follows: Ballast, 3,280,094 tons valued at \$471,008; fills and similar purposes, 274,303 tons valued at \$36,091.

6 May include some gravel used by railroads for fills and miscellaneous purposes.

Noncommercial operations.—Segregation of sand and gravel reported by States, counties, municipalities, and other local Government agencies was begun during the 1932 canvass, when it was found that these noncommercial operations were producing an increasing percentage of the total annual output. Noncommercial production increased from 5 percent of the total production in 1928 to 39 percent in 1933; and, although the tonnage remained about the same in 1934 and 1935, because of increased commercial production it comprised only 35 and 32 percent, respectively, of the total. Preliminary data indicate an increase of roughly 35 percent in 1936, the estimated quantity of 53,000,000 tons comprising 31 percent of the total sand and gravel accounted for. (See fig. 90.)

The average value of all noncommercial material reported in 1935 was \$0.27 a ton, whereas the indicated average in 1936 was \$0.30. Of the 1935 total, 22,011,231 tons valued at \$0.22 a ton was produced directly by construction or maintenance crews of States, counties, municipalities, and other local Government agencies, while 17,305,221 tons valued at \$0.34 a ton was produced by contractors expressly for the use of such agencies. State highway departments accounted for 56 percent of the total output; counties, 40 percent; municipalities, 3 percent; and other agencies, 1 percent.

Sand and gravel sold or used by producers in the United States, 1932-36, by commercial and noncommercial operations

[Figures for "noncommercial operations" represent tonnages reported by States, counties, municipalities, and other Government agencies, produced either by themselves or by contractors expressly for their consumption, often with publicly owned equipment; they do not include purchases from commercial producers. Figures for "commercial operations" represent tonnages reported by all other producers including relatively small amounts of railroad ballast and fill produced directly by railroad carriers for their own use]

Year	Commercial operations		Noncommercial operations ¹		Total accounted for	
	Short tons	Percent of change from preceding year	Short tons	Percent of change from preceding year	Short tons	Percent of change from preceding year
1932.....	85,289,076	-33.9	34,748,821	+41.6	120,037,897	-21.8
1933.....	66,106,472	-22.5	41,648,877	+19.9	107,755,349	-10.2
1934.....	75,322,909	+13.9	² 41,288,780	- .9	116,611,689	+8.2
1935.....	84,607,471	+12.3	³ 39,316,452	-4.8	123,923,923	+6.3
1936 ⁴	119,660,000	+41.4	53,000,000	+34.8	172,660,000	+39.3

¹ Part of the apparently large increase in noncommercial production is due to more nearly complete reports in the later years.

² Includes 20,314,296 tons valued at \$0.22 a ton produced directly by construction and maintenance crews of States, counties, municipalities, and other Government agencies and 20,974,484 tons valued at \$0.40 a ton produced by contractors expressly for the use of such agencies. Various agencies reported production as follows: States, 27,950,916 tons valued at \$0.35 per ton; counties, 11,382,718 tons at \$0.18; municipalities 631,461 tons at \$0.23; and others, 1,323,685 tons at \$0.67.

³ Includes 22,011,231 tons valued at \$0.22 a ton produced directly by construction and maintenance crews of States, counties, municipalities, and other Government agencies and 17,305,221 tons valued at \$0.34 a ton produced by contractors expressly for the use of such agencies. Various agencies reported production as follows: States, 22,016,880 tons valued at \$0.32 per ton; counties, 15,965,458 tons at \$0.20; municipalities, 1,027,130 tons at \$0.32; and others, 306,984 tons at \$0.73.

⁴ Subject to revision.

Commercial production of sand and gravel for building and paving is centered largely in the Mid-Atlantic and Mid-Western States, with California, Texas, and Washington as the large producers elsewhere. Noncommercial production, on the other hand, looms large in New England, North Central, and Rocky Mountain States. (See fig. 91.)

FIGURE 90.—Sand and gravel sold or used in the United States by commercial and noncommercial producers, 1928-36. Figures for 1936 are subject to revision.

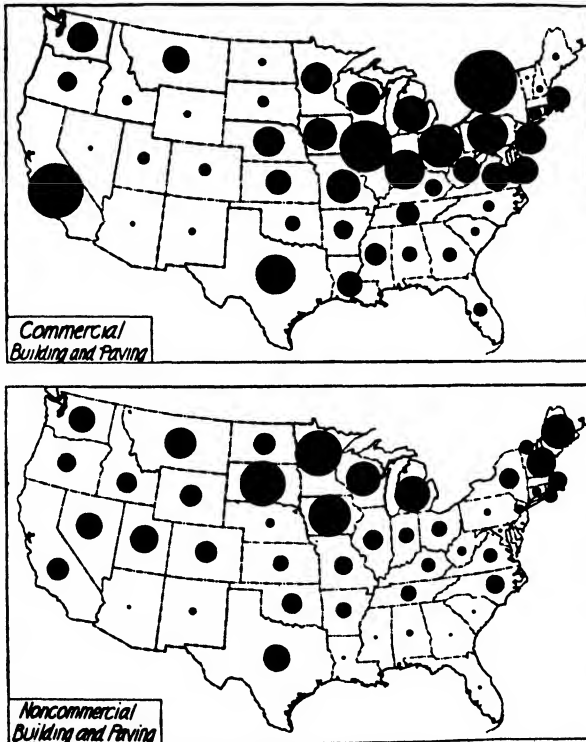

FIGURE 91.—Building and paving sand and gravel sold or used by commercial and noncommercial producers in 1935, by States. Areas of circles represent tonnage.

With the possible exceptions of Minnesota, Iowa, Wisconsin, and Michigan, most of the large noncommercial operations serve States where road materials are not available from commercial plants. The small noncommercial output reported in several States, notably Arizona and New Mexico, may be due to lack of complete data.

Method of transport.—Shipments of sand and gravel originating on class I railroads in 1936 totaled 40,213,215 short tons, an increase of 32 percent over 30,451,218 tons in 1935. This quantity represented 40 percent of total commercial production, exclusive of glass and molding sand and nonrevenue railroad ballast, compared with 43 percent in 1935. The trend from 1928 to 1933 was toward increased truck shipments of sand and gravel with the railroads carrying a smaller percentage of the total each year. In 1934 and 1935, however, rail shipments were relatively larger, indicating at least a temporary break in the increasing use of truck transportation, which apparently again was greater in 1936. (See fig. 92.)

FIGURE 92.—Shipments of sand and gravel, by modes of transportation, 1928-36. Data on rail shipments are from reports of the Interstate Commerce Commission; to insure comparability, glass and molding sand, railroad ballast, and noncommercial production have been excluded from the figures used in the comparisons. Figures for 1936 are subject to revision.

Producers making nearly 90 percent of the total commercial output of sand and gravel in 1934 and 1935 reported the methods by which their product was transported. According to these figures, as summarized in the following table, waterway shipments in 1935 increased slightly at the expense of both rail and truck. Comparable data for 1936 are not yet available.

*Sand and gravel sold or used by commercial producers in the United States, 1934-35, by methods of transport*¹

	1934		1935	
	Short tons	Percent of total	Short tons	Percent of total
Shipped by—				
Truck.....	21,447,749	31.7	23,480,830	31.3
Rail.....	38,762,817	57.4	42,318,644	56.4
Waterway.....	7,358,533	10.9	9,273,258	12.3
	67,569,099	100.0	75,072,732	100.0
Percent of total commercial production accounted for..	89.7	-----	88.7	-----

¹ For practical purposes the entire output of noncommercial operations commonly is moved by truck. Including noncommercial production, sand and gravel were moved as follows—1934: Truck 58 percent, rail 35 percent, and waterway 7 percent; 1935: Truck 55 percent, rail 37 percent, and waterway 8 percent.

Preparation.—In both 1934 and 1935 by far the larger part of the output of commercial operations was washed, screened, or otherwise prepared, whereas most of the noncommercial production was pit-run material. The average value per ton of prepared material was more than double that of unprepared.

Sand and gravel (prepared or unprepared) sold or used by producers in the United States, 1934-35, by commercial and noncommercial operations

	1934			1935		
	Short tons	Average value per ton	Percent of total	Short tons	Average value per ton	Percent of total

Unprepared.....	31,877,585	.24	77.2	32,007,653	.22	81.4
	41,288,780	.31	100.0	39,316,452	.27	100.0

Size of plants.—In 1927 the Bureau of Mines compiled a table showing production of sand and gravel by size of companies.² A similar, although not absolutely comparable, compilation was made by size of plants for 1931³ and in the following table for 1935. A definite trend toward production of an increasing percentage of total output by small plants is apparent. This, however, indicates decreased output of existing plants in the later years as well as introduction of smaller producing units. In 1931, 32 percent of the total output was reported by plants producing less than 100,000 tons each, but this same-size group in 1935 accounted for 42 percent of the total. Regardless of this trend, however, the large plants still account for an appreciable part of the output; in 1935, 36 plants amounting to only 2 percent of the total number of plants reported 27 percent of the total production.

Number and output of commercial sand and gravel plants in 1935, by size groups¹

Size group (short tons)	Plants ¹			Production		
	Number	Percent of total	Cumulative percent	Short tons	Percent of total	Cumulative percent
Less than 25,000.....	1,139	61.17	61.17	9,501,000	11.23	11.23

⁵ Minerals Yearbook, 1932-33, p. 609.

PRICES

Despite increased demand for sand and gravel for all uses in virtually every section of the country, average prices in 1936 showed little change from 1935. The average value per ton, f. o. b. plant, for all sand and gravel reported by commercial producers remained unchanged at \$0.61. A slight weakness in sand prices resulted in a drop of 2 cents a ton in the average value of sand, but it was balanced by an advance of 2 cents for gravel.

Preliminary data indicate a slight increase in the average value of sand and gravel used in construction but a drop of 5 percent in that sold for paving. As building and paving combined account for about 80 percent of total sales by commercial producers, it is evident that any weakness in prices of these materials is reflected strongly in the average value of the product of the sand and gravel industry as a whole. The average value of the various industrial sands changed little from 1935. The rise in average value of both sand and gravel sold for miscellaneous uses shows the result of the omission in 1936 of large quantities of low-priced fill reported in 1935 for use in the construction of Fort Peck Dam. The indicated rise in average value of material produced at noncommercial operations may be due to the inclusion of a larger percentage of prepared material in 1936.

According to data presented at the annual meeting of the National Sand and Gravel Association, price declines were sharpest in the New York City area and in California, where price cutting at times during 1936 assumed the appearance of a price war. On the other hand, slightly increased prices were reported in Arkansas, Minnesota, Oklahoma, Texas, and western Pennsylvania. Apparently there was little change throughout the rest of the United States.

Wholesale price indexes of the Bureau of Labor Statistics, although based on relatively small samples, confirm the preliminary data on unit values. The price index of building sand dropped from 98.7 in 1935 to 98.2 in 1936, and that of gravel increased slightly—from 89.6 to 90.8.

MARKETS

About 80 percent of the sand and gravel produced at commercial operations in 1936 entered some form of building or highway construction. Indicators of these markets, therefore, are useful in following trends in demand for sand and gravel. Cement, paving asphalt, and cut-back asphalt shipments advanced 50, 36, and 44 percent, respectively, in 1936 compared with 1935. Furthermore, concrete-pavement contract awards were 31 percent higher and the value of construction contracts awarded increased 45 percent. These data substantiate the evidence of incomplete returns from producers, upon which the preliminary production figures for 1936 are based.

Sales of road oil in 1936 increased only 21 percent, although an advance of at least 35 percent in production of noncommercial pit-run material for use on low-type roads is indicated. The use of calcium chloride and even common salt in so-called "stabilized roads" is growing, but no data are available to show exact trends in use of these materials.

¹² American Railway Association.

Increased ballast expenditures by class I railroads in 1936 confirm the indicated sharp advance in sales of sand and gravel ballast. Greater activity in glass plants, foundries, rail traffic, stone-finishing mills, and industry in general was responsible for increased sales of industrial sands.

NEW DEVELOPMENTS

Plant improvements in the sand and gravel industry in 1936 were designed to meet more rigid specifications for a wider variety of products. The increasing demand for a wider range of sands containing a higher percentage of finer sizes was an outstanding trend in the industry. Increased use of gravel, particularly crushed gravel in the finer sizes, in bituminous mixtures was also noteworthy. Producers have been able to meet changing demands, but lack of uniformity in specifications among Government agencies has resulted in higher costs for even the large operations. On the other hand, further progress was made during 1936 in standardizing aggregates used in highway construction. Several additional States revised their specifications to follow the recommendations of the Division of Simplified Practice and changed from round to square openings in test screens.

Foster and Walker ⁴ reported the results of research on strength and wear tests of gravel and crushed-stone-concrete. They concluded that the shape of the particles has little effect on strength, although

⁴ Foster, Alexander, Jr., and Walker, Stanton, *Wear and Strength Tests of Gravel and Crushed-Stone Concretes*: Nat. Sand and Gravel Assoc. (mimeographed preprint), 1936, 20 pp.

rounded aggregates permit the use of a richer mortar because of the lower percentage of voids. Of particular interest was their finding that crushed stone rounded mechanically and used in concrete gave the same compressive and flexural strengths as angular crushed stone with the same cement content.

Several companies are operating mixing plants to prepare material for so-called "stabilized roads." Sand, gravel, and clay are mixed in the proper proportions with calcium chloride, sodium chloride, or possibly some other binding agent, and trucked to the job. This type of construction is becoming increasingly popular for low-cost secondary roads but probably does not afford a wide market for permanent plants, except under special conditions.

The use of conveyor belts for pit to plant and intraplant movement of materials apparently is increasing. The installation at Grand Coulee Dam has attracted much attention.⁵

A series of reports by J. R. Thoenen,⁶ of the Bureau of Mines, covering prospecting, development, and operation of sand and gravel deposits was completed early in 1936. Some of these reports are now out of print, but the others may be procured from the Publications Section, United States Bureau of Mines, Interior Building, Washington, D. C. Copies are available for reference in virtually all libraries.

Health problems in the industry, particularly with respect to silicosis, received greater attention during 1936.

The National Industrial Sands Association was formed in April 1936. Producers of industrial sands first felt the need of an organization during the days of NRA and until the formation of the new association were organized as a division of the National Sand and Gravel Association.

FOREIGN TRADE ⁷

Imports of sand and gravel are confined largely to movements of aggregates across the United States-Canada boundary and to shipments of Belgian glass sand, mostly consigned to the Pacific coast glass industry. Exports likewise are principally aggregates moving into Canada.

Domestic gypsum.....	1231		
Imported gypsum.....	1232		

As a result of continued improvement in the gypsum industry during 1936 production and sales reached the highest levels since 1930. The output of crude gypsum rock and gypsite from mines in the United States in 1936 was 2,712,510 short tons, or 42 percent more than the 1,903,880 tons obtained in 1935. Augmented by 661,595 short tons of imported crude rock, new supplies of gypsum in 1936 totaled 3,374,105 tons. Figure 93 shows trends in the gypsum industry from 1927 through 1936.

FIGURE 93.—Trends in domestic production, imports, and total supply of crude gypsum in the United States, 1927-36. Imports include small amounts of ground and calcined gypsum.

Sales of products made from domestic gypsum in 1936 were valued at \$26,222,377. They included 752,625 short tons of uncalcined material valued at \$1,458,123, sold as cement retarder, as land plaster, and for miscellaneous purposes, and 1,730,687 tons of calcined products

valued at \$24,674,254, used principally as building materials. These amounts represent substantial increases over sales in 1935, when the total value was \$18,860,348, including 520,594 tons of uncalcined material valued at \$1,039,979 and 1,233,816 tons of calcined products valued at \$17,820,369. Total sales of products manufactured from both domestic and foreign gypsum in 1936 were valued at \$32,-954,558, 39 percent more than in 1935 and the highest since 1930.

Salient statistics of the gypsum industry in the United States from 1932 to 1936 are summarized in the following table.

¹ Gypsum and gypsum products produced from rock of both domestic and foreign origin.

² Includes calcined gypsum sold to other manufacturers and for miscellaneous uses.

³ Includes ground and calcined gypsum and Keene's cement, but not "Manufactures of which plaster of paris is the component material of chief value n. s. p. f." (principally statues, art goods, and novelties).

⁴ Comparable data not available.

⁵ Includes raw and calcined gypsum and gypsum products.

The rise in imports from 1925 to 1930 (see fig. 93), when domestic production and sales were dropping, resulted from an increase in the number of calcining plants erected along the Atlantic seaboard. The aggregate increased capacity of such plants consequently moderated the decline in imports after 1930, although the output of some operations using imported crude declined in about the same proportion as that of operations using domestic material.

General improvement in the gypsum industry was caused almost entirely by the rise in volume of building construction. (See fig. 94.) The Federal Reserve Board index of total construction, based on the 1923-25 average as 100, advanced from 37 in 1935 to 55 in 1936, an increase of 49 percent, which corresponds rather closely to the 42-percent rise in gypsum production. The gypsum industry was aided particularly by the 60-percent increase in privately financed con-

struction, principally for buildings, which furnished by far the greatest demand for gypsum products.

FIGURE 94.—Crude gypsum production compared with value of construction contracts awarded, 1927-36. Construction indexes compiled by the Federal Reserve Board.

DOMESTIC PRODUCTION

In 1936 crude gypsum was supplied by 65 mines operated in 17 States by 36 companies. Five operations, each of which includes an underground mine and a quarry, have been counted as 10 mines. About 60 percent of the total output was obtained from 36 underground mines, mostly in the East and Middle West. The remaining 40 percent was extracted from 28 quarries located principally in the West and Southwest, although 3 large operations in the Middle West (1 in Iowa and 2 in Michigan) supplied a considerable part of the total open-pit tonnage. Gypsite was produced at 10 quarries in 5 States.

Production increased in all States except two that always furnish relatively small amounts. The four leading States, in the order of their importance, were New York, Michigan, Iowa, and Texas, and their combined output (1,707,809 short tons) accounted for 63 percent of the total.

¹ Each mine, plant, or combination mine and plant is considered as 1 establishment.

² Included under "Other States."

³ Arizona, Idaho, Kansas, Montana, Ohio, South Dakota, Utah, Virginia, and Wyoming.

⁴ Also includes sales from California, Colorado, Nevada, and Oklahoma.

Employment.—The improved employment situation at the mines in 1936 clearly reflected the stimulation of production resulting from the greater demand for gypsum. A comparison of data for 41 identical mines which supplied 74 percent of the total output indicates not only an increase of 23 percent in the number of men employed in 1936 compared with 1935 but also an average gain of 43 working days, which combined resulted in a 51-percent rise in the number of man-shifts. The decline in production per man-shift may have been caused by increased maintenance and development work, which had been reduced to a minimum in previous years when operating economies were necessary.

Employment and production at 41 identical gypsum mines, 1935-36 ¹

Year	Employment			Production			
	Number of men	Average number of days	Number of man-shifts	Short tons	Percent of total	Per man-shift (short tons)	Per man-year (short tons)
1935.....	873	187	163,252	1,488,070	78.2	9.1	1,705
1936.....	1,074	230	246,777	1,992,475	73.5	8.1	1,855

¹ Includes 28 underground and 13 open-pit mines.

Calcining.—Gypsum of domestic and foreign origin was calcined during 1936 at 52 plants in 16 States. Of these plants, 41, most of which were adjacent to mines, calcined domestic gypsum and gypsite, and 11 on the East and West seaboard used only imported crude rock. In all, 187 kettles and kilns were operated, with a total daily capacity of 27,962 short tons. The reduction in capacity of 1,033 tons from 1935, which occurred in spite of the operation of two additional plants, resulted from the operation of eight fewer kettles and one less kiln.

Active calcining kettles and kilns in the United States in 1936, by States

³ Arizona, California, Connecticut, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, and Vermont.

DISTRIBUTION OF SALES

Domestic gypsum.—Most sales of domestic gypsum comprise calcined products used as building materials. In 1936 these products totaled 1,621,401 short tons, including the weight of admixtures such as fiber, sand, hair, and paper, and were valued at \$23,768,386. Obviously, the increases in this classification of 43 percent in quantity and 41 percent in value over 1935 were responsible for most of the gain in total sales of all products. Sales of base-coat plasters again led all other items in value, although before 1935 sales of wallboard had led for many years. The most outstanding development was the rise in sales of plaster board and lath to a new all-time peak of 255,688 short tons valued at \$5,601,619. The greatest value previously reported for these products was \$4,260,087 in 1930, and the largest quantity was 252,813 short tons in 1928. Substantial increases over 1935 were also shown in sales of all other products except insulating materials, which declined about 50 percent. The largest increase occurred in the classification "Other building purposes." This includes for the most part joint filler and patching plaster, which are sold in small quantities at relatively high prices, accounting for the high value per ton.

Calcined gypsum for manufacturing purposes is sold principally to plate-glass, terra-cotta, and pottery works. Sales to all classes of consumers except pottery works gained over 1935, resulting in total increases of 21 percent in quantity and 12 percent in value.

Trends in sales of uncalcined gypsum are influenced largely by demands from portland-cement manufacturers who require raw gypsum as a retarder in their product. Consequently, the 41-percent increase in quantity sold for that purpose in 1936 follows closely the 49-percent gain in cement shipments during the year. The slight rise in quantity of agricultural gypsum sold was characteristic of the trend in consumption of all fertilizers, although the value was some-

what less than in 1935. Sales of gypsum in 1936 "For other purposes" were about double those in 1935, owing to a greater demand for fillers.

Crude gypsum, and gypsum products made from domestic crude gypsum, sold or used by producers in the United States, 1935-36, by uses

Grand total value		18,860,348		26,222,377

¹ Includes gypsum sold for paper or other filler, insulating materials, paint manufacturing, and rock dust.

² 1935: 191,289,518 square feet; 1936: 362,533,715 square feet.

³ 1935: 211,042,247 square feet; 1936: 295,458,380 square feet.

⁴ 1935: 6,954,337 square feet; 1936: 10,207,546 square feet.

⁵ Includes joint filler, patching and acoustic plaster, roofing tile, other tile, and pyrofill.

⁶ Includes dental plaster, hydrocal, coecal, casting and molding plaster, paper and paint filler, and stucco.

⁷ Includes calcined gypsum sold to other manufacturers and for miscellaneous uses.

Imported gypsum.—Sales of products manufactured from imported gypsum were valued at \$6,732,181 in 1936 and comprised 20 percent of the total value of products made from both domestic and foreign gypsum. The increase over 1935, amounting to 40 percent, was virtually the same as the 39-percent rise in sales of products made from domestic rock. Gains occurred during 1936 in sales of all classifications of calcined products except molding plaster, the decline in which was more than offset by the unusually large sales of finishing plasters. The quantity and value of sales of the uncalcined products were also larger in 1936, although sales of agricultural gypsum, the most important item in the group, declined slightly. Sales to cement mills increased 142 percent in value, and sales of uncalcined gypsum for other purposes (which were almost negligible in 1935) were 5,504 tons, valued at \$66,087, in 1936. It was used mostly as filler.

Imported crude gypsum, and gypsum products made from imported crude gypsum, sold or used in the United States, 1935-36, by uses, as reported to the Bureau of Mines by the importers

¹ Includes calcined gypsum used for Keene's cement, plasterboard, lath, wallboard, roofing tile, insulating materials, and other building purposes, and calcined gypsum sold to other gypsum manufacturers and for miscellaneous uses.

² Includes gypsum sold to potteries and for other manufacturing uses.

PRICES

Average values per ton of gypsum products, f. o. b. mills, as reported by producers, are used to indicate trends in prices, as market quotations are not available for many of the producing sections of the country. Prices thus indicated declined slightly in 1936, contrary to the Bureau of Labor Statistics indexes for all commodities and for building materials in general, which gained 1.0 and 1.6 percent, respectively. A 3-percent drop in unit value of raw sales was influenced by agricultural gypsum, which was valued at \$4.25 per short ton in 1936, compared with \$5.34 per ton in 1935, and by sales "For other purposes", which declined from \$2.18 in 1935 to \$2.12 in 1936. The increase in value of gypsum sold to cement mills from \$1.79 a ton in 1935 to \$1.81 in 1936 prevented a more drastic reduction in the average value of all material sold raw. The average values of gypsum sold for use in cement manufacture varied considerably in different States, ranging from \$1.05 to \$2.93 per ton.

The small decline in the average value of calcined products was caused by a drop of \$4.35 per ton in the price of wallboard and smaller decreases in prices of building plasters despite gains in the unit value of Keene's cement, and plasterboard and lath. The range in average values of some of the more important products was: Base-coat plaster, \$5.85 to \$10.55 per ton; wallboard, \$28.71 to \$41.71; and plasterboard and lath, \$19.06 to \$35.46.

The realization per ton on gypsum mined, computed by dividing the total sales value by the number of tons produced, indicates fairly well the general trend in average prices of all products. The value of \$9.67 in 1936 was 2 percent lower than in 1935 but still was considerably higher than in 1934 and previous years.

Average values per short ton of gypsum and gypsum products (made from domestic crude gypsum) sold or used by producers in the United States, in selected years from 1910 to 1936

¹ Figures not available.

² Includes Keene's cement and some dental plaster and other products.

³ Includes some dental plaster and other products.

⁴ The increase in this item before 1925 was due largely to increasing integration, as some wallboard and other high-priced products were made by plants owned by gypsum producers instead of outside plants purchasing their raw or calcined gypsum from the primary producers.

⁵ Calculated by dividing total value of all sales by tons of crude gypsum mined.

NEW DEVELOPMENTS

Increased demand for gypsum products and generally higher prices encouraged more plant improvements and expansion in 1936 than had taken place in many years. Additional properties adjoining old workings were acquired by at least one company. Plants on the East coast using imported rock, and mines in Canada supplying them, were acquired by one of the larger domestic producers. A new mine was opened in Idaho which produced a small amount of rock by the open-pit method for use as cement retarder. Tube milling continued to be a live topic, and tube mills were installed for the first time by a few producers.

An electric furnace for calcining gypsum was described ¹ as having the essential advantage of regulation and maintenance of the optimum temperature. By elimination of the hot flame, the ordinary heavy kettle can be replaced by one of light construction. The power consumption in practice is 160 to 180 kilowatt-hours per 1,000 kilograms of gypsum, varying with the water to be driven off.

FOREIGN TRADE ²

Imports.—Foreign trade in gypsum consists mainly of imports of crude rock from Canada. Most of the material is obtained from quarries near tidewater in Nova Scotia and New Brunswick and shipped by boat to ports on the New England and Mid-Atlantic seaboards. Mexico, which ranks second as a source of imported gypsum, annually supplies less than 10 percent of the total. The

¹ Pit and Quarry, vol. 29, no. 5, November 1936, p. 70.

² Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

rock from that source is quarried in Lower California and transported in boats to the larger ports on the West coast.

Imports of crude gypsum in 1936 were 661,595 short tons valued at \$620,943 and, as in former years, exceeded the tonnage and fell short of the value furnished the Bureau of Mines by importers. Imports other than crude consisted of raw ground gypsum, calcined gypsum, plaster of paris, and Keene's cement. The only substantial gain was in the value of plaster of paris—\$34,722 in 1936 compared with \$20,958 in 1935.

¹ Quantity not available.² Value for calcined included with "Crude, crushed, or ground "³ Value for "Plasterboard and wallboard" included with "Plaster, calcined, and manufactures, n. e. s "**WORLD PRODUCTION**

The widespread occurrence of gypsum and its low value per ton in the crude form, which limits its transportation to relatively short distances, have encouraged production in virtually all parts of the world. Total world production reached a peak of 13,000,000 metric tons in 1929. Declines in the next 4 years reduced the quantity to 7,400,000 tons in 1933, but since then gains have been made annually. Only partial data are available for 1936, but the upward trend apparently continued.

The United States, normally the largest gypsum-producing country in the world, has been exceeded as a producer by France since 1931. Other large producers in the order of their importance are Great Britain, Germany, Spain, U. S. S. R. (Russia), Italy, and Canada. The output in Great Britain has been maintained at a high level for a number of years due to an extensive building program undertaken there during the depression. Germany, too, has had a relatively high production for several years, and if more complete figures were available Germany might prove to be even nearer the lead as a world producer.

Canada, which ranks about eighth in volume of output, has a greater export trade in gypsum than any other country, due to the proximity of the eastern deposits to tidewater and cheap transportation to large population centers in the United States. Moreover, trade with Great Britain has been stimulated by affiliation of producers in Canada with manufacturers in England and by the relative proximity of the new operation at Cape Breton, which is about a third of the way from New York to England.

World production of gypsum, 1932-36, by countries, in metric tons

Agricultural lime and other liming materials.....	1245	Hydrated lime.....	1254
Hydrated lime.....	1246		

Sales of lime, which increased substantially during 1935, attained much higher levels in 1936. According to preliminary figures sales by producers in 1936 totaled 3,783,000 short tons valued at \$27,464,000, an increase of 27 percent in quantity and 26 percent in value over 1935. The average value per ton was \$7.26 in 1936 compared with \$7.28 in 1935. Sales of hydrated lime in 1936, which are included in the total given above, were 1,216,000 short tons valued at \$9,700,000, an increase of 21 percent in quantity and 22 percent in value compared with 1935. The average value per ton of hydrated lime was \$7.98 in 1936 and \$7.90 in 1935.

The table of salient statistics shows sales by uses. The most striking increase was in shipments of building lime; the gain of 41 percent reflects the substantial improvement in construction during 1936. Although building contracts reached 55 percent of the 1923-25 average, sales of building lime were only 39 percent of the maximum reached in 1925. Lime has evidently lost ground to competitive products in this important field.

Shipments of dead-burned dolomite for use as a furnace refractory (557,000 short tons valued at \$4,693,000) advanced 22 percent in quantity and 24 percent in value over 1935. The production of steel ingots increased 43 percent, but a similar gain in consumption of refractories was not to be expected as the large sales in 1934 and 1935 covered both current requirements and the accumulated demand due to postponement of purchases during the depression years. The foregoing figures do not cover the entire consumption of dead-burned dolomite, because some steel companies calcine dolomite which they purchase raw. Such purchases are recorded in the chapter on Stone under shipments of raw dolomite.

Shipments of chemical and fluxing lime reached 1,988,000 short tons valued at \$12,651,000, a gain of 25 percent over 1935. This gain may

¹ Figures for 1936 are preliminary; detailed data with final revisions will be released later.

be attributed partly to greater steel-making activity as about one-third of the lime included in this category is used in iron and steel works. The use of lime in water purification has increased notably. Likewise, most of the chemical and manufacturing industries employing lime, especially paper mills, tanneries, glass factories, and miscellaneous chemical works, increased their consumption.

Shipments of agricultural lime (315,000 short tons valued at \$2,128,000) increased 11 percent.

The following table summarizes the principal statistics of the lime industry in 1936 compared with 1935.

1935.....	301	2,987,133	21,748,655	7.28
1936 ²	300	3,783,000	27,464,000	7.26

¹ Value given represents value of bulk lime f. o. b. at point of shipment and does not include cost of barrel or package.

² 1934: Includes 129,290 short tons valued at \$671,864, used by producers (captive tonnage); 1935: 143,716 tons valued at \$750,155.

³ Subject to revision.

Production by States.—Data are not yet available on production by States for 1936. The following table shows output by States for 1935. Ohio leads, and Pennsylvania stands second. These two States together produced over 41 percent of the total. Other States producing more than 100,000 tons each, in order of importance, were Missouri, West Virginia, Tennessee, Virginia, Alabama, and Illinois.

Lime sold or used by producers in the United States in 1935, by States

Hydrated lime.—Lime in hydrated form is more satisfactory than quicklime for many uses, therefore it has become an important product of the lime industry. The following table shows sales for the past 5 years.

Hydrated lime sold or used by producers in the United States, 1932-36

Building lime.—Because of limited activity in building during the depression years, sales of building lime were at a low ebb, but they increased substantially in 1935 and 1936. Preliminary figures show sales of 923,000 short tons valued at \$7,992,000 in 1936 compared with 656,894 tons valued at \$5,716,802 in 1935. Building lime is an important product in Ohio. The following table shows sales in that State from 1933 to 1935.

*Lime sold or used by Ohio producers for construction, 1933-35*¹

	1933		1934		1935	
	Short tons	Value	Short tons	Value	Short tons	Value
Quicklime.....	1,941	\$11,807	2,628	\$17,080	2,650	\$17,695
Hydrated lime.....	214,019	1,294,394	183,032	1,472,590	245,580	2,165,002
	215,860	1,306,201	185,660	1,489,670	248,230	2,182,697

¹ Ohio produced 40.5 percent of the total building lime sold by producers in 1933, 36.3 percent in 1934, and 37.8 percent in 1935.

Chemical lime.—The chemical and manufacturing uses of lime have made large gains during recent years. If refractory lime (dead-burned dolomite) is included the total lime so used has increased from 1,663,591 tons in 1934 to 2,047,579 in 1935 and approximately 2,545,000 in 1936. Sales according to the principal chemical uses are shown in the table on page 1242. The following table shows sales of lime in 1935 for minor chemical uses that are designated "Other uses" in the previous table.

Chemical lime sold or used by producers in the United States for "Other uses" in 1936

¹ Lime used in alcohol manufacture, asphalt filler, bichromates, bituminous concrete materials, bromine, calcium carbonate, calcium gluconate, cement, cinder blocks, corn products, cream of tartar, creameries and dairies, disinfectants (chloride of lime, etc.), dyes, explosives, flour mills, iron oxide, lubricants, magnesium oxide, oxygen purification, potassium citrate, retarder, sanitation, slag cements, sodium citrate, soil erosion, sulphur, textiles, and whitening.

Agricultural lime and other liming materials.—Sales of lime for agriculture fluctuate less than for other major uses. In 1934, 222,077 short tons were sold; in 1935, 282,660 tons; and in 1936, approximately 315,000 tons. Materials used for liming land include quicklime, hydrated lime, lime from oyster shells, crushed oyster shells, raw pulverized limestone, and calcareous marl. The following table shows sales of these products in 1935 and 1936.

Agricultural lime and other liming materials sold by producers in the United States, 1935-36, by kinds

TRENDS IN PRINCIPAL USES

Figure 95 shows trends in the principal uses of lime from 1915 to 1936. Total production in 1936 increased more than in any year since the bottom of the depression in 1932. The chief increases from 1932 to 1935 were in chemical lime, but in 1936 the principal gain was in building lime. Trends in the average value per ton and in the number of plants in operation are also shown.

Figure 96 shows the relation between sales of building lime and volume of construction for a 10-year period. A steady gain in this market may be anticipated if the volume of building attains the proportions expected.

FIGURE 95. Trends in the principal uses of lime, number of plants, and average value per ton, 1915-36

FIGURE 96.—Value of sales of building lime compared with value of construction contracts awarded, 1927-36. To facilitate comparison unlike units have been reduced to percentages of the 1923-25 average. Statistics for lime are from the Bureau of Mines; those for construction compiled by the Federal Reserve Board from data of the F. W. Dodge Corporation.

Figure 97 shows the relation of sales of fluxing and refractory lime (dead-burned dolomite) to output of steel ingots from 1927 to 1936. The remarkable activity of steel plants in 1936 has so fostered this market that sales were at a higher level than in predepression years.

FIGURE 97.—Sales of fluxing and refractory lime compared with steel-ingot production, 1927-36. To facilitate comparison unlike units have been reduced to percentages of the 1923-25 average. Data on production of steel ingots compiled by American Iron and Steel Institute.

NEW DEVELOPMENTS

In May 1936 the Bureau of Mines published Information Circular 6884, entitled "Lime." It covers briefly the history of lime manufacture, raw materials, kinds of lime produced, uses, quarrying and manufacturing methods, and marketing.

A new type of heat- and sound-insulating building material known as microporite has been developed in Europe for interior use. Fine silica dust is mixed with lime and water, molded, and treated with steam for 7 hours. The process is similar to that employed in the manufacture of sand-lime brick, but the reaction is more rapid and complete. The units are strong, although they weigh only 25 to 50 pounds per cubic foot. A large Canadian lime producer is conducting exhaustive research on the manufacture of this product.

Many improvements were made in plant equipment in various parts of the country in 1936. Several lime-putty plants were completed; some of them furnish aged putty, for which certain advantages are claimed.

It has been found that hydration of lime can be accelerated by the addition of small percentages of salts, such as sodium hydroxide.

Experiments conducted in Europe indicate that the hardening and setting of lime mortar are not due primarily to carbonation but to drying and shrinking of the calcium hydroxide gel. Short cycles of partial drying and rewetting increase the strength greatly.

An innovation in the lime industry is the installation by the Chemical Lime Co., Bellefonte, Pa., of a 400-foot rotary kiln. The purpose of the kiln is to obtain slow calcination at a relatively low temperature and to attain a large productive capacity. About 3 hours elapse from the time the limestone enters the kiln until it is discharged as lime, and the maximum temperature attained is about 2,200° F. It is expected that 200 tons of chemical lime will be produced daily.

PRICES

The average value of lime, f. o. b. plant, dropped steadily from 1923 to 1932 when it was only \$6.28 a ton. The value remained unchanged in 1933, advanced to \$7.16 a ton in 1934, rose to \$7.28 in 1935, and remained fairly steady in 1936 at an average of \$7.26. The price of agricultural lime increased 3 cents a ton; building lime dropped 4 cents; chemical lime dropped 14 cents; and refractory lime (dead-burned dolomite) rose 11 cents a ton in 1936. The average sales value of hydrated lime at the centers of production rose from \$7.90 a ton in 1935 to \$7.98 in 1936.

As indicated in figure 95 the average value of lime is still much lower than in 1926. The price index of lime (1926=100) was 78.6 in 1934, 79.9 in 1935, and 79.7 in 1936. The price indexes of all building materials for the same years were respectively, 86.2, 85.3, and 86.7. Therefore, the recovery in prices of lime has not kept pace with that of building materials in general.

FOREIGN TRADE ³

Imports.—Total imports of lime for consumption in the United States in 1936 were nearly twice as great in quantity and 85 percent greater in value than in 1935. The largest increase was in imports of dead-burned dolomite, the use of which has been stimulated greatly by the high level of activity at steel plants. The following tables show imports for a series of years and imports for 1935 and 1936 by countries:

Lime imported for consumption in the United States, 1932-36

Year	Hydrated lime		Other lime		Dead-burned dolomite		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1932.....	1,677	\$18,756	7,100	\$77,279	5,120	\$115,808	13,897	\$211,843

SHIPMENTS

Total shipments.—Shipments of lime, as reported to the Bureau of Mines by producers, are combined in the following table to show, for 1935, total sales by States, shipments from each State, shipments into each State, probable consumption or supply in each State, and per-capita consumption. The figures in the second table are arranged to show the quantities of lime originating in and destined for State groups that approximately comprise various freight-rate zones. The figures in the second table do not include small quantities produced in Hawaii and Puerto Rico, foreign shipments, or lime for which distribution is not recorded. No account is taken of reshipments beyond the destination indicated when the lime left the producing plant. Similar figures for 1936 are not yet available.

Lime supplies available for consumption in continental United States in 1935, by States, in short tons

Fire clay.....	1259	Prices.....	1265
Stoneware clay.....	1260	Consumption and uses.....	1266
Bentonite.....	1260	The industry in foreign countries.....	1269

In 1936 the production and sales of domestic kaolin broke all previous records, and sales of merchant clay generally continued their upward trend. More domestic clay was exported than in any earlier year, and although imports of china clay and certain other kinds of clay were slightly greater than in 1935, they were far less than in pre-depression years. Prices were unchanged or only slightly higher, but, owing to larger-scale operations, the industry as a whole enjoyed a prosperous year. Improvement was most marked in the production of higher-grade clays. The heavy-clay-products industries and even the industries using fire clays have so far failed to recover all the ground they lost after 1929, although their condition has improved sharply from the extreme depression of 1932. The pottery industry, too, has failed to regain its former importance, and several other ceramic industries have lagged behind the general recovery, which partly explains the much reduced consumption of sagger clays. More clay was used in making firebrick in 1936 than in any previous year, according to the Bureau of Mines records, and the refractories industries as a whole were in healthy condition. The most spectacular increase was in the use of domestic clay in paper making, sales to that industry having been almost 40 percent greater in 1936 than in 1930, the former record year. The consumption of clay by the rubber industry, which only recently has become an important buyer of such material, increased to an even greater extent, though not so significant from a tonnage standpoint, accounting for almost twice as much clay in 1936 as it did before 1933.

High lights in the following summary table, which compares pre-war, predepression, and recent years, are the general rise in domestic production and exports and the decline of imports.

Salient statistics of the clay industry of the United States, 1909-13 and 1925-36

¹ Sales of bentonite included under "Miscellaneous clay" before 1930.

² Includes fuller's earth, previously reported in a separate chapter in Minerals Yearbook or Mineral Resources volumes.

³ Statistics of exports of clay not separately recorded before 1916.

⁴ Includes fuller's earth.

CLASSIFICATION

The industrial uses of clays differ almost as much as do their chemical and physical attributes. For a decade or more, the Bureau of Mines clay-production statistics have represented chiefly clay mined and sold as clay, mined under royalty, or shipped into another State for fabrication. In effect, this classification includes most of the high-grade kaolins, ball clays, slip clays, and bentonites used for fine ceramic wares, paper making, and general industrial purposes, plus a considerable part of the fireclays used in the manufacture of refractories and most of the fireclays used for other purposes. It excludes most of the clays and shales used in making common brick, sewer pipe, and other heavy-clay products or in cement manufacture. The present chapter in general follows this same classification, except that it includes also fuller's earth, formerly discussed in a separate chapter of Minerals Yearbook.

Most clays have the property of bleaching oil to a greater or less extent, hence fuller's earth is merely a clay that is used commercially in the raw state for decolorizing or bleaching oils and fats. Certain other clays, notably bentonite, develop this property to an even higher degree when treated with acid, but earth so activated is not classed by the Bureau of Mines as fuller's earth, even though used for much the same purposes.

The term "clay" includes a great variety of substances that may differ widely in chemical, mineralogical, and physical properties. Virtually all clays comprise a number of minerals. Even pure kaolinite ($\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2 \cdot 2\text{H}_2\text{O}$), which is ordinarily considered to be the

typical "clay substance", recently has been found to exist as three distinct minerals, and each of these in turn exhibits variations in particle size and other physical attributes. In addition to the kaolin minerals and other relatively simple aluminum silicates, almost all clays contain quartz, feldspar, and mica with varying amounts of organic matter and, in addition, other impurities—such as iron, manganese, and titanium oxides—that may discolor them sufficiently to render them unfit for certain important uses. The white clays are generally the purest, but no two are really alike, and great care must be exercised to maintain a reasonable uniformity in successive shipments, even from the same deposit. Defloculation and sedimentation processes, which hitherto have represented the best clay-washing practice, are inadequate for any but size separations; but improved technique, including the application of froth flotation, may permit commercial fractionation and recombination of natural clays from different banks so as to yield well-standardized products. Under these circumstances, the various rule-of-thumb classifications of clays that have developed may lose their significance. Already the Bureau of Mines, in cooperation with the Tennessee Valley Authority and private clay companies, has devised methods for manufacturing from domestic clays a uniform reproducible product of high-grade kaolin equal to the best Czechoslovak porcelain clay. To develop markets for local clay, the Tennessee Valley Authority has laid the foundations of a ceramic industry in the South that for the first time will use electrically-heated kilns for making pottery. At Boulder Dam, the Bureau of Mines likewise has demonstrated the feasibility of firing pottery products electrically so as to afford outlets for local clays in that vicinity.

DOMESTIC PRODUCTION

China clay or kaolin.—The production of kaolin or china clay jumped to 638,939 short tons valued at \$4,537,738 in 1936 compared with a previous high record of 533,800 tons valued at \$3,893,814 in 1930. Georgia as usual was the leading producer, contributing 66 percent of the total; South Carolina was second with 20 percent; and Pennsylvania is the only other State that produced as much as 5 percent of the total, although its output is considerably less valuable than that of Florida, which does not produce the cheaper grades of kaolin. The dominance of Georgia is exaggerated somewhat by the inclusion since 1931 of certain hard or so-called "flint" kaolins as kaolin rather than, according to use, as fireclay. Accordingly, a break-down of the Georgia figures is submitted in an accompanying table.

Increased sales in 1936 were well distributed among consuming industries, of which the paper industry is most important, as it accounts for about two-thirds of the total sales of this class of clay. The rubber and ceramics industries, each of which takes about 15 percent of total sales, also were more prosperous in 1936. Larger and larger quantities of clay are going into paint and miscellaneous products. In the paper industry the use of calcium carbonate sludge has increased substantially, but the use of clay, more especially of domestic clay, has increased even more. Improvement in demand for paper clays in 1936 was accelerated by a relatively large increase in book-paper requirements by the large magazines. Most periodicals of the class that use high-grade paper increased their bulk as well as their circulation as a result of an increase in advertising by companies

having a Nation-wide distribution of their products. Moreover, larger percentages of clay are being used in such papers; instead of an average content of 7 percent ash, as formerly, many book papers now have an ash content of 14 to 20 percent, occasionally higher. Then, too, foreign clays have been displaced largely by domestic clays, except in certain localities where freight rates are unduly disadvantageous to American miners; and talc, which was used a great deal 20 years ago, likewise is employed only where it has an overwhelming advantage in delivered cost. By active research the quality of domestic clays has been improved progressively, and new varieties have been developed. American clays, formerly used as additions to the beaters (filling), are gaining ground rapidly in the coating field, for which processed clays costing \$30 and even \$60 a ton are now available. Some of these high-priced clays may replace much of the satin white employed in high-grade coated paper, with an indicated saving in casein consumption.

Ball clay.—Ball clays are highly plastic, strong, and white to cream in color. Geologically they represent the finest of the pure clay substance that remains suspended for the longest time in lakes or swamps; often they contain a little lignite. Toughness is a characteristic

property, and the presence of adsorbed salts or electrolytes is indicated. Ball clays also differ from kaolins in that their average particle size is measurably smaller. Domestic ball clay is mined principally in Kentucky and Tennessee, although minor amounts so classed are produced in New Jersey, Maryland, Missouri, and Illinois. They are used chiefly in white earthenware and porcelain but are employed also in floor and wall tile, electrical porcelains, certain glass refractories, and graphite crucibles, chiefly mixed with china clay in the body as a bonding agent and to impart plasticity and, in refractory mixes, to make them workable. Brief descriptions of the Tennessee-Kentucky ball-clay operations have been published recently.¹

Slip clay.—Slip clays are fine-grained and somewhat similar to ball clays, except that they contain a high percentage of iron and manganese, so that they melt to greenish or brown glass at relatively low temperatures. The use of slip clays for glazing stoneware is decreasing, as they are being displaced for this purpose by artificial white glass. So-called slip clays are mined in the United States only in New York, Pennsylvania, and (occasionally) Michigan. The quantity has become quite small, in recent years rarely exceeding 5,000 tons annually. Although separately reported by the Bureau of Mines in previous years, henceforth they will be included in the classification "miscellaneous clays." At present they are employed principally for binding abrasive wheels, although minor quantities are still used for glazing pottery, tile, and other fired products.

Fireclay.—Fireclays withstand high temperature and usually are not fusible below about 3,000° F. (cone 27 or 28). In collecting statistics, the Bureau of Mines will attempt later to distinguish between (a) plastic fireclays, (b) flint clays, and (c) high-alumina or burley clays. Although the main use of fireclays is for refractories of various kinds, chiefly firebrick, many of the miners of these clays find markets for a portion of their output in other industries, including some purposes for which other kinds of clay might be equally suitable. On the other hand, certain kinds of kaolin, notably the hard or flint kaolins of Georgia and Pennsylvania, are used in refractories, as are also small quantities of bentonites and other clays. In short, the term "fireclay" is employed rather loosely and is not confined strictly to refractory

clays, nor does it include all clays used in making refractories. In the present review stoneware clays, formerly reported separately, are included in the Bureau of Mines figures with fireclay. For 1936, moreover, the schedule employed for reporting production was altered to indicate more definitely what clay was used at the plant where it was produced and what clay was sold or shipped elsewhere. This change, too, tends to make the figures not quite comparable with those of former years.

Although fireclay occurs in all but about a dozen States and is mined in at least 30, Pennsylvania, Ohio, Missouri, Kentucky, and California together contribute over 75 percent of production, about one-third of the total coming from Pennsylvania alone.

¹ Includes diaspora and burley clay as follows: 1934, 20,294 tons, valued at \$104,692; 1935, 23,248 tons, valued at \$104,316; 1936, 33,584 tons, valued at \$150,455.

Stoneware clay.—Stoneware clays are produced principally in Ohio and Illinois and are used not only for stoneware but also for yellow ware, art ware, earthenware, and even for terra cotta. The classification obviously is arbitrary and overlaps that for fireclay. The ideal stoneware clay has a long vitrification range and vitrifies at a lower temperature than does ordinary fireclay, but these requirements along with the desired plasticity, toughness, and bonding strength, are generally obtained by mixtures of different clays, including plastic fireclay, flint fireclay, and more or less ball clay. Actually, more "fireclay" than "stoneware clay" has been used in making chemical and other stoneware, and the quantities classified by the producers as "stoneware clay" in their reports to the Bureau of Mines have diminished greatly during the last several years. After review of these facts, the classification has been eliminated from certain tabulations in this chapter, and clay that formerly would have been so designated has been included under the broader classification "fireclay."

Bentonite.—Bentonites are "soapy" clays composed of weathered and altered volcanic ash. They are characterized by an extraordinary capacity to take up many times their own volume of water (adsorption). Their chief use is for oil-well drilling muds to maintain

suspensions, but their thickening and suspending properties are utilized in many other industries, and substantial quantities are employed in foundries for rejuvenating molding sand and as a core wash. Most of the activated earths employed for bleaching oils are acid-treated bentonites. Another use of great practical importance, though not constituting a regular outlet for much tonnage, is for sealing dams and for rendering water-bearing gravels and seamy rock impervious. Probably the most typical bentonite is found near Belle Fourche, S. Dak., and in an adjoining area in eastern Wyoming, although it occurs in at least a dozen States, and commercial shipments were reported in 1936 from 8 States.

² Includes output of "rotary mud" in California, amounting to 95,043 tons, valued at \$175,967.

Fuller's earth.—The production and consumption of fuller's earth in the United States increased in 1936, but the increase was small compared with that in petroleum refining. The only State to show an important expansion in production was Texas; output in several other States declined. The aggregate production was 230,814 tons valued at \$2,264,978; and the indicated consumption, as calculated by adding imports and deducting exports, rose 2 percent to 227,429 tons compared with 222,520 tons in 1935. The Federal Reserve Board index of petroleum refining, however, jumped more than 10 percent, the yearly average of 181 exceeding the previous record of 168 in 1929 by a wide margin, whereas the apparent quantity of fuller's earth used was 25 percent less than in 1929 and 31 percent less than in 1930, when it reached its maximum of 328,642 tons.

Over 90 percent of the domestic fuller's earth sold is used for refining petroleum products; 5 to 7 percent is used for clarifying, bleaching, decolorizing, or filtering animal and vegetable oils; and an almost negligible amount, in some years less than 1 percent, is used for miscellaneous purposes. The statistics show quite positively that consumption of fuller's earth in the United States has not kept pace with the growth of the petroleum industry in recent years. To be sure, there is no really accurate barometer of the potential demand for fuller's earth or the amount of decolorizing that has to be done, because no data are available as to the proportion of possible lubricants removed at lubricating-oil refineries, where most of the fuller's earth is used. Nevertheless, the fact remains that relative quantities of fuller's earth have diminished since 1930—whether the comparison is

made on the basis of crude-oil production, deliveries to refineries, or lubricant production. The obvious conclusion is that much of the expanded consumption of artificially activated earths, made from bentonite, and of acid-sprayed earths, such as are produced especially in Texas, have invaded the market for fuller's earth. New methods of oil refining likewise have threatened to diminish the use of fuller's earth, but inquiries in the trade lead to the conclusion that chemical processing of lubricating oils may have been overdone and that even oils so processed generally require some treating with fuller's earth. There is a feeling, too, that the recent trend away from percolation methods and in favor of contact methods may be now in reverse, a fact of importance to the fuller's-earth industry, inasmuch as the finer grades used in contact refining sell for only about \$6.50 a ton as against \$10 to \$12.50 a ton for coarser grades such as are used for percolation.

FIGURE 98.—Consumption of fuller's earth compared with petroleum refining activity, 1919-36. To facilitate comparison the tonnage of fuller's earth has been reduced to percentages of the 1923-25 average. The petroleum-refining index is compiled by the Federal Reserve Board.

Progress is being made in finding uses for spent earth. It may be too much to expect that earth will be thrown away after being used only once, but if the spent earth could be disposed of profitably there would be less incentive for revivifying it after its efficiency had been impaired substantially. For about 5 years a leading California cement company has been making a weatherproof portland cement by adding to the clinker before grinding about 3 percent of spent clay containing 20 to 30 percent carbonaceous matter. The process (U. S. Patent 1755638) yields a cement that is at least as strong as ordinary portland cement, although it does not mature so rapidly. Additional uses for spent earth have been noted by Kauffman.²

Miscellaneous clay.—Except for slip clay, which appears in the miscellaneous group this year for the first time, the material included in this group by the Bureau of Mines consists chiefly of shale and common clays of low unit value and used mostly for making sewer pipe, common brick, and other heavy-clay products. Most clays of this class do not find their way into the Bureau of Mines statistics because they are fabricated at integrated plants. Only under certain circumstances can these clays be transported economically more than a very short distance from the pit from which they are dug. This classification should not be interpreted as representing "all other clays" produced in the United States but not included under more specific designations. In addition to clays made locally into heavy-clay products or used in cement manufacture, the Bureau of Mines statistics exclude, also, ochers, umber, and other colored clays and earths used as pigments.

The geographical distribution of this group of clays is shown in the following table.

Heavy-clay products.—Employment in brick, tile, and terra-cotta works in the United States rose sharply in the early months of 1936 but failed to advance much beyond 50 percent of the 1923-25 average, the index for the 12-month period being 45.6 compared with 36.3 for 1933, an increase of 25 percent.

Production statistics for heavy-clay products are compiled by the Bureau of the Census, which reported that in 1935 the value of all clay products, exclusive of pottery and nonclay refractories, made in the United States was \$89,989,246 compared with \$66,179,814 in 1934. For common brick alone the value rose from \$11,419,108 to \$18,246,059 reflecting a volume increase from 1,099 millions in 1934 to 1,806 millions in 1935. For clay firebrick the value rose from \$15,485,175 to \$19,496,590 and the quantity from 390 to 482 millions. Corresponding

figures for 1936 have not been compiled, but available data indicate that increases from 1935 to 1936 were even greater than from 1934 to 1935—though still far below the predepression totals, due to the continued lag of building activity behind the recovery in general business.

FOREIGN TRADE ³

Imports.—Kaolin or china clay comprises the bulk of the clays imported into the United States. These clays come principally from England, although small quantities are imported from Germany and other countries. Notwithstanding a substantial increase in imports in 1936, the amount of foreign clay used in the United States today is scarcely 40 percent of the average annual imports from 1925 to 1929. Compared with pre-war averages, imports of china clay in 1936 had been virtually halved, whereas domestic production was more than four times as large. The next largest item in the import statistics is "common blue and ball clays", imports of which were reported separately in 1936 for the first time and amounted to 30,021 short tons valued at \$271,359. These clays likewise come principally from England, and the importations obviously increased in 1936, reflecting greater activity in tile and sanitary ware plants. Formerly included in the same category were Gross Almerode glass-pot clays, a well-known German product, imports of which in 1936 amounted to 2,145 short tons valued at \$26,852. Gross Almerode clay has a low shrinkage, high binding power, and high refractoriness; but one of its chief claims to superiority is the ease with which it disintegrates in water and the remarkable uniformity with which water distributes itself through the mass. The composition of some of these clays closely resembles that of china clay, except for an iron oxide content of about 2 percent. Most samples, however, also contain about 1 percent lime.

English ball clays are still preferred by some potters to American clays of this class. They have a much lower melting point, as a class, than the Kentucky-Tennessee ball clays.

Fuller's-earth imports have followed a general downward trend since 1914 and declined further in 1936. Virtually all are from the United Kingdom.

¹ Imports of Gross Almerode clay reported separately in 1936—2,145 tons valued at \$26,852.

³ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Exports.—Kaolin, ball clay, glass-pot clay, common fire clay, and fuller's earth are the only crude clays that enter international trade to any extent. For many years, fire clay was the only American clay exported regularly in large tonnages, and it still is the only clay for which separate export statistics are compiled by the Bureau of Foreign and Domestic Commerce. In earlier years, the other high-grade clays were chiefly imported and domestic producers, having difficulty in gaining markets even in their own country, made little effort to seek foreign markets.

Following the better standardization and general improvement in quality of American clay, this condition has been changed. Beginning in 1923, the Bureau of Mines has been able to report exports of fuller's earth from returns furnished directly by producers, and in 1936 replies to its questionnaires indicated substantial exports of bentonite, ball clay, slip clay, and even kaolin. Strange as it may seem, in view of the extensive imports of china clay from these countries, American kaolin was shipped in 1936 even to England and Germany, though not, of course, in large amounts.

Fire clays are exported to Canada, Europe, and South America. Domestic clays of this class are of good quality and some of the deposits are relatively close to the Atlantic seaboard. Whereas the average value of domestic fire clay, f. o. b. mines, in 1936 was \$2.48 a ton, the export valuation was \$6.64 a ton. The latter figure may include freight to port of shipment but, even so, the spread is sufficient to indicate a considerable proportion of processed clay.

The Bureau of Mines returns do not account for the relatively large quantities of unspecified clays reported in the Bureau of Foreign and Domestic Commerce export statistics shown in the Salient Statistics table earlier in this chapter. This is probably due to the fact that much of this business is handled through dealers or custom grinding mills. Nevertheless, the returns from producers tend to show that bentonite enjoys the most widely diversified foreign markets; Canada is the principal consumer, but small shipments are made to Europe, South America, and the Far East. Exports of fuller's earth declined in 1936; Canada and Germany are the leading consumers, but smaller shipments were reported to U. S. S. R. (Russia), Mexico, South American countries, and Cuba.

PRICES

Prices of clay were generally firmer in 1936, although the calculated average sales realization for domestic kaolin dropped slightly to \$7.10 compared with \$7.19 per ton in 1935. Trade-journal quotations remained virtually unchanged. According to the Engineering and Mining Journal, South Carolina and Georgia china clay was worth \$6 to \$7 a ton, crushed, pulverized, or air-floated, and \$7.50 to \$8.50 a ton, water-washed, f. o. b. mines in bulk; \$2.50 extra was charged for shipment in 50-pound paper bags. Both grades of Florida clay (super-white and super-plastic), washed and crushed, were \$11.75 a ton; Delaware clays \$14 a ton; New Jersey plastic kaolin, pulverized, in paper bags, was \$10; and Pennsylvania clay, crude, ground, was \$6 a ton, f. o. b. mines. For bentonite, f. o. b. Wyoming mines, the quotation was \$8 in bulk and \$10 in bags for crude clay (dried and crushed), whereas selected air-floated bentonite was quoted at \$25 a ton at Chicago. Fuller's earth was quoted at \$9 a ton (probably

crude) f. o. b. Colorado and \$17 to \$21 (ground earth) f. o. b. California. F. o. b. Georgia or Florida mines, quotations were \$14.50 per ton for 30- to 60-mesh, \$14 per ton for 15- to 30-mesh, \$10 for 200-mesh up, and \$7 for 100-mesh up. These prices for fuller's earth are almost identical with those for 1935 but are substantially lower than those quoted before the depression, particularly with respect to coarser grindings. Compared with predepression quotations, the figures for china clay likewise are lower but the difference is not so great.

Prices of imported clays were increased somewhat in 1936 because of higher ocean rates. On English clays there was a freight advance on cargo shipments from 14s. to 15s., even higher rates being asked during the weeks when war seemed imminent. On German clays freight rates advanced from \$3.75 at the beginning of the year to \$4 a ton in December.

The average valuations of several kinds of clay and fuller's earth as reported by producers are shown in the following table.

Average values per short ton of various kinds of clay sold by producers in the United States, 1909-13 and 1925-36

Year	Kaolin		Ball clay	Slip clay	Fire clay and stone-ware clay	Bentonite	Fullers' earth
	United States	South Carolina					
1909-13 ¹	\$5.34	\$3.88	\$3.65	\$1.81	\$1.36	(?)	\$9.27
1925-29 ¹	8.45	8.93	7.67	5.41	2.74	(?)	13.95
1930-34 ¹	6.44	6.83	7.16	6.83	2.59	\$6.17	10.62
1935.....	7.19	7.57	6.55	5.99	2.64	5.68	9.79
1936.....	7.10	7.53	6.87	6.37	2.48	5.37	9.81

¹ Average.

² Sales of bentonite not reported separately before 1930.

Prices of common brick, as measured by the composite figure of the United States Bureau of Labor statistics, continued to decline, although only slightly, the average for 1936 being \$11.753 per thousand compared with \$11.768 in 1935. The low point was in 1933, when the average was \$10.53 as compared with around \$14 during most of the 10 years prior to 1930.

CONSUMPTION AND USES

The Bureau of Mines began in 1921 to collect data on the distribution of sales of domestic clay according to uses, but these figures do not accurately depict trends of consumption of pottery clays, paper clays, and sundry minor items consumed in industries that are gradually turning away from foreign clays in favor of domestic clays. However, the accompanying table, showing sales of clays by producers, kinds, and uses for 1935 and 1936, affords a fair comparison of actual conditions in the consuming industries during these years, more particularly so because imports are smaller than previously and fluctuate less from year to year.

The feature in the table showing distribution of fuller's earth is the notable increase in the consumption for miscellaneous uses, which include miscellaneous bleaching and filtering as well as use as filler and binder. None is employed nowadays for the original use for fulling cloth.

Clay sold by producers in the United States, 1935-36, by kinds and uses, in short ton

THE INDUSTRY IN FOREIGN COUNTRIES

The world-wide struggle of nations to become self-sufficient with respect to their mineral supplies has altered the international movement of raw clay, and several foreign countries, as well as the United States, have greatly reduced their dependence upon English clays. Other countries have built kilns and factories so as to diminish their imports of pottery, refractories, and other clay products. New discoveries in Belgium have revived kaolin mining at Malvoisin, long abandoned. The Burma China Clay Works, Ltd., a new firm, is reported by vice consul Lyle C. Himmel, Rangoon, to be producing high-duty fire brick and fire clay from pits at Yinnye-in, Thaton District, Burma. The interest, growing for some time, in utilizing low-grade kaolin deposits in northeastern Hungary by means of a sedimentation process is confirmed by a report that two new companies were organized in 1936 to produce high-quality china clay and paper clay, respectively. Italian developments include a new undertaking in Agro, county of Cossoine, Sardinia. Portugal, too, now has an established china- and paper-clay mining industry.

The Canadian situation is summed up in the following extract ⁴ from a report (no. 773) of the Mines Branch, Department of Mines, Ottawa:

There is a steady demand for various grades of china clay in Canada for use in the manufacture of paper and rubber as well as in the ceramic industry. Ball clays are used in the ceramic industry as a bonding clay in the manufacture of porcelain and similar compounded bodies. While the market in Canada is not large, it is growing and there are also good prospects of developing a profitable export market in the United States. Ball clays of high bond strength occur in extensive deposits in southern Saskatchewan. Deposits of high-grade, white-burning clays occur on Mattagami, Abitibi, and Missinaibi Rivers in northern Ontario. Some of these clays may be classed as ball clays and others as china clays; recent developments at two points in this area will probably result in a small production of clay in the near future. The only place where china clay has been produced commercially in Canada is near St. Remi d'Amherst, Quebec. There are numerous occurrences of clay of bentonitic type in the Prairie Provinces and several deposits are also known in British Columbia. The greater part of the small domestic production has come from deposits at Princeton, British Columbia.

Further recovery was reported by the British clay industry. Exports of china clay from Cornwall amounted to 449,381 long tons in 1936, compared with 430,465 tons in 1935, due to increased sales to the United States and Germany, the leading consumers. English China Clays, Lovering, Pochin & Co. Ltd., the largest producers of china clay in the United Kingdom, installed a new power plant that was said to have cost £110,000 (\$550,000) ⁵ thereby indicating optimism as to the future of the industry as well as a purpose to reduce production costs.

The commercial sources of magnesium are considered in this chapter but not magnesium itself, which now ranks as a fairly important metal. Henceforth, magnesium, instead of being included in the same chapter as its compounds, will be considered in a separate chapter of the Minerals Yearbook.

The interchangeability of magnesium raw materials has become of more than academic interest. Nominally magnesite still heads the list of magnesian minerals, but in 1936 brucite was mined on a commercial scale for the first time. The recovery of magnesium salts from natural brines is increasing. In the United States, magnesium metal is still made exclusively from magnesium chloride of brine-well origin, but it may be feasible later to make it from magnesite or dolomite, as is done abroad. Basic carbonate, formerly obtained exclusively from the treatment of dolomite, is now extracted from the raw sea water of San Francisco Bay.² In Germany the method of obtaining magnesium compounds from dolomite by treating the calcined mineral with magnesium chloride (so as to form magnesium hydroxide) has been improved, under an I. G.-controlled process, by directing the reaction between dolomite or limestone and magnesium chloride liquor (probably a potash-works byproduct) so as to recover the magnesia as anhydrous neutral carbonate that settles readily.³ According to British Patent 442764 the operation is conducted in an autoclave at 150° C. The Pattinson process still accounts for most of the magnesium compounds produced from dolomite, at least in the United States; however, there are numerous other processes, and if any of these prove much cheaper the recovery of magnesium compounds from dolomite may increase. In Japan⁴ a new firm has undertaken to make purified magnesium carbonate by calcining Korean and Manchurian magnesites, leaching out the magnesium hydroxide, and reprecipitating the solution with the carbon dioxide from the calcining process.

¹ Figures on imports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

³ Chemical Trade Journal (London), Mar. 27, 1936, p. 261.

⁴ Chemical Age (London), Magnesium Carbonate, Vol. 34, no. 867, Feb. 8, 1936, p. 130.

Probably no other development so clearly reveals the complete interchangeability of magnesium raw materials as does the decision of the Westvaco Chlorine Products Corporation (which, through a subsidiary organization, has been one of the two large producers of magnesite) that it is more economical under present conditions to produce about 25,000 tons a year of dead-burned refractory magnesite from California salt-works bitterns than to open a new mine in that State. The product of the new chemical plant, construction of which was begun early in 1937, will be comparable in chemical composition and price to the dead-burned product made from natural magnesite.

MAGNESITE

Sales of both foreign and domestic magnesite in the United States increased sharply in 1936 owing to increased steel-making activity and notwithstanding the large purchases made in 1935 for the purpose of again building up stocks to normal. The desire to rebuild stocks was stimulated somewhat further by the tense situation that threatened to cut off supplies from Mediterranean ports, but even so the 37-percent increase in apparent supply of dead-burned magnesite failed to equal the 40-percent increase in domestic steel production over 1935. There was a small increase in the use of caustic calcined magnesite, although the 7,998 tons reported in 1936 represents only a fraction of the 42,654 tons supplied in 1924, when the use of magnesium oxychloride cements for stucco and flooring reached its maximum in the United States. Possible revival of their use, however, is forecast as a result of laboratory investigations at the Mellon Institute of Industrial Research. By the addition of 10 percent of finely divided copper powder, many of the shortcomings of magnesium oxychloride cements appear to be eliminated and their useful field correspondingly widened. During the time the cement is hardening and for long periods afterward, the metal is converted to a new cementing material that resembles the natural mineral, atacamite ($\text{CuCl}_2 \cdot 3\text{Cu}(\text{OH})_2$).⁶ Apparently several times as much caustic calcined magnesite is now used in the United States as a chemical accelerator in rubber as is used in oxychloride cements. Although the quantity of these cements used in stucco has decreased, the quantity employed in flooring and wallboard has increased. Caustic calcined magnesite is also used as a base for magnesium salts and for heat-insulating materials.

¹ Partly estimated; most of the crude is processed by the mining companies, and very little enters open market.

² Average receipts f. o. b. mine shipping point.

³ Revised figures.

FIGURE 99.—Apparent new supply of caustic calcined and dead-burned magnesite in the United States from domestic and foreign sources, 1923-36.

DOMESTIC PRODUCTION

Following a 75-percent increase in the production of crude magnesite from California and Washington in 1935 over the previous year, the output in 1936 rose to 207,119 short tons, a 17-percent increase over

1935 and the largest reported since 1920, when 303,767 tons of crude magnesite were mined in the United States. Of the 1936 output, only 1,669 tons, valued at \$24,420, were sold as crude. The total value of the mine output in 1936 is estimated at \$1,411,664, but this value is purely nominal, as the mining companies convert most of the material into dead-burned or caustic calcined magnesite.

Only two companies mined domestic magnesite in 1936; but recovery of byproduct magnesite is anticipated in Vermont, and production of brucite in Nevada has already begun on a commercial scale.

California.—The California Chemical Co. (220 Bush St., San Francisco, Calif.), formerly a subsidiary of United Chemicals Co., operated the Robert Hays Smith mining property about 28 miles north of Patterson throughout 1936. This mine, which was purchased in 1935, has been worked out and now is permanently closed; all usable equipment was moved away during the first quarter of 1937. The crude ore from the property was converted almost entirely into dead-burned magnesite and periclase grain in the rotary kiln at Patterson which was leased and rehabilitated for that purpose. Company operations at both its Bald Eagle and Western mines were continuing at full capacity after the close of 1936, but these properties were unable to supply the increased demand. Production of dead-burned magnesite by the company henceforth will be augmented by the synthetic product to be made from salt-works bittern in its new chemical plant. The output of the Bald Eagle mine in Stanislaus County is shipped from Ingomar and that of the Western mine (Santa Clara County) from Livermore. Each of these mines is equipped with oil-fired rotary kilns producing both dead-burned and caustic material. The Western mine, formerly known as the Red Mountain, is leased from the Western Magnesite Development Co. and operated through tunnels. Early in 1936, 40 men were reported as being employed at this property, of whom 10 were in the 20-ton mill; 117 men were working at the Bald Eagle mine, of whom 12 were in the 50-ton mill at that property. On January 30, 1937, complete control of the California Chemical Co. was acquired by Westvaco Chlorine Products Corporation.

Nevada.—During the depression, the Standard Slag Co., of Youngstown, Ohio, relinquished its lease on the Springer claims near Luning, Nev., and the U. S. Brucite Corporation was dissolved. The property is now owned by the U. S. Brucite Co., of which Dr. Thomas R. Haig, of Sacramento, Calif., is president. In October 1936 operations were begun under lease by Basic Dolomite, Inc. (845 Hanna Bldg., Cleveland, Ohio), which made substantial shipments to its eastern plant before the end of the year when operations were suspended temporarily owing to an unprecedented snowfall. It is expected that several thousand tons of brucite will be required annually as a base for the material to be sold under the trade name "Thomasite" covered by United States Patent 1965605.

Vermont.—The Eastern Magnesia Talc Co. (Burlington, Vt.) continued its flotation tests made in cooperation with the Bureau of Mines and in 1936 was building a plant which began operating in February 1937. Besides increasing recoveries and improving the quality of the talc, the new plant is expected to produce a tailing of magnesite low in lime and silica but fairly high in iron. Details of marketing this product had not been worked out by the end of 1936.

Washington.—The Northwest Magnesite Co. (executive offices, Farmers Bank Building, Pittsburgh, Pa.) continued to operate its Finch mine and produced considerable magnesite from the nearby Allen-Moss quarries, from which shipments were first made in 1917 by the American Mineral Production Co. All holdings of the latter concern were acquired in 1923 by the Northwest Magnesite Co., which is the only operator in the State. The calcining equipment at Chewelah, comprising six rotary kilns capable of handling a total of 300 tons daily, was operated at more than 50-percent capacity during 1936. In addition to dead-burned magnesite a moderate quantity of caustic-calcined magnesite is made for use in the manufacture of the insulating and fireproofing product which the company markets under the trade name "Thermax."

IMPORTS

Notwithstanding the substantial increase in domestic production, imports of dead-burned magnesite increased notably in 1936 and those of caustic calcined material increased a little. Imports credited to Austria, which as usual was the principal source of dead-burned magnesite, increased proportionately more than total imports. The so-called magnesitic dolomite produced in Argenteuil County, Quebec, and formerly imported as "magnesite", is now classified for customs purposes under paragraph 214 of the Tariff Act of 1930 and more specifically provided for under the Reciprocal Trade Agreement with Canada, effective January 1, 1936, as "dead-burned basic refractory material containing 6 percent or more of lime and consisting chiefly of magnesia and lime." Statistics of imports of this material are given later in this chapter under "Dolomite."

Magnesite imported for consumption into the United States, 1935-36, by countries and classes

Country	Crude		Caustic calcined				Dead-burned, and grain and periclase	
	Short tons	Value	Lump		Ground		Short tons	Value
			Short tons	Value	Short tons	Value		
1935								
Austria							12,765	\$216,937

Netherlands	48	1,112	124	3,304	645	18,049		
Norway							35	2,513
U. S. S. R. (Russia)							4,655	74,030
United Kingdom			1	152	79	2,796		
Yugoslavia					188	5,075		
	89	1,130	1,245	22,553	951	27,121	42,608	662,567

PRICES

The quotations reported for magnesite in 1935 were unchanged in 1936. Dead-burned magnesite remained at \$22 per short ton f. o. b. Chewelah, Wash., and \$25 per ton f. o. b. California mines, equivalent to about \$35 a ton delivered at Pittsburgh, Pa. High-grade periclase (94-percent grade) continued to be quoted at \$65 and the 90-percent (actually about 92-percent) grade at \$35 a ton f. o. b. California shipping point. The top price for caustic calcined magnesite was still \$40 per ton for the 95-percent grade.

Import valuations tended to be somewhat lower in 1936 than in 1935, but much of the variation can probably be explained by differences in the basing point, as import valuations are calculated f. o. b. foreign shipping point. A shipment of Austrian magnesite, for example, would be worth nominally more if invoiced from the Italian port of Trieste than from the mines.

THE INDUSTRY IN FOREIGN COUNTRIES

*World production of magnesite, 1931-35, by countries, in metric tons*¹

¹ Unless otherwise stated quantities in this table represent crude magnesite mined.

² Magnesitic dolomite.

³ Data not available.

⁴ Exports, less imports, of crude and sintered magnesite, the sintered being reduced to crude on the basis of 2.1 tons crude to 1 ton sintered.

⁵ Year ended Sept. 30.

⁶ Serbia only.

Austria.—Due to increased shipments to the United States, exports of dead-burned magnesite from Austria rose to 63,944 metric tons, compared with 55,121 tons in 1935. Great Britain, second largest buyer of Austrian dead-burned magnesite, increased its purchases very slightly, while sales to other countries, especially to Germany, generally declined. Exports of caustic calcined magnesite, most of which go to Germany, increased to 43,968 metric tons as against 34,317 tons during 1935, the small exports of crude magnesite advanced moderately to 9,203 metric tons in 1936 from 7,169 tons in 1935. Less magnesite bricks and plates were exported to Germany and Italy, but larger sales to Great Britain and France resulted in an increase for these items also; the total exports in this category were 39,263 metric tons in 1936 compared with 35,960 tons during 1935.

Crude magnesite was exported in 1936 only to Germany where it is used at Bitterfeld for the manufacture of magnesium. This magnesite is low in iron (1½ percent) and comes from the Zillerthal mine of the Alpenländische Bergbau Gesellschaft (owned by Friedrich Krupp Gesellschaft, Essen, Germany).

The Wald magnesite mine belongs to the Alpine Montan Gesellschaft, Vienna, and is worked only to provide refractories for steel plants owned by that company.

The bulk of the Austrian output is furnished by three companies. The largest is the Veitscher-Magnesitwerke A. G. (capital 7,500,000 schillings) which operates three mines and employed an average of 950 men in 1936. This company produces only dead-burned magnesite, about 40 percent of which it manufactures into brick or other shapes. It exports 90 percent of its product. The Oesterreichisch-Amerikanische Magnesit A. G. (capital 14,000,000 schillings) employs about 750 men and produces chiefly dead-burned magnesite and magnesite brick for export and caustic calcined magnesite and dust for making floor tile and insulating board (Heraklith). The Steirisch Magnesit Industrie A. G. (capital 2,000,000 schillings), the third largest producer, is not a member of the European cartel and sells only caustic calcined magnesite, 90 percent of which is exported to Germany.

Export prices of Austrian magnesite declined in 1936. The price of dead-burned magnesite during the first 9 months of 1936 was 159.79 schillings a metric ton compared with 167.83 schillings during 1935. The export price of bricks and plates declined about 4 percent from the 1935 average to 387.22 schillings per metric ton, and that for caustic calcined magnesite also dropped about 4 percent to 98.95 schillings. The average exchange rate for the Austrian schilling was \$0.1879 in United States currency in 1936 and \$0.1883 in 1935.

Canada.—"Magnesitic dolomite" is produced in Argenteuil County, Quebec, about 60 miles west of Montreal and north of the Ottawa River, by the International Magnesite Co., Ltd., and Canadian Refractories, Ltd. The latter company reduces the crude rock to about 100 mesh and then dead-burns it in rotary kilns. The value of production and statistics of imports of this material into the United States are given later in this chapter, under "Dolomite."

*Chosen (Korea).*⁶—Two companies are producing magnesite in northern Chosen, near Gosui, North Kankyo Province; the calcined product, including some magnesite brick, is shipped to Japan.

Greece.—After exports of magnesite had declined sharply in the first quarter they resumed their upward trend, and shipments increased substantially in 1936 over those in 1935. As usual the Netherlands was the largest buyer, especially of the crude product. Shipments of crude totaled 45,290 metric tons; of caustic calcined 23,716 tons; and of dead-burned magnesite 11,985 tons. Corresponding figures for 1935 were 33,502 tons, 22,502 tons, and 9,191 tons, respectively. No shipments to the United States were reported either in 1935 or 1936.

India, British.—Magnesite from Madras is principally high grade, and suitable for making sord cement and plastic products; for use by the local steel industry it is mixed with 2 percent iron ore and burned into brick at 1,600° C.

Italy.—According to a report ⁷ from American Vice Consul William

⁶ Langdon, Wm. R. (U. S. Consul, Seoul), Mineral Trade Notes; Bureau of Mines, vol. 2, no. 6, June 1936, pp. 21-22.

⁷ U. S. Bureau of Mines, Mineral Trade Notes: Vol. 3, no. 2, August 1936, pp. 15-16.

P. Shockley, Jr. (Leghorn), magnesite occurs abundantly in the hills about 2 km east of the Tyrrhenian Sea and about 3 km north of the town of Castiglioncello, Commune Rossignana Marittima, Leghorn Province. Deposits in this region were worked actively during the World War, and although much of the magnesite produced therefrom has been unmarketable it is believed that commercial operations might be resumed successfully under adequate technical supervision. In analysis the Castiglioncello magnesite is more like the Austrian than the Greek product. Evidently it has to be sorted rather carefully but the following analysis is given as representative of "material that can be utilized": Magnesia, 42.45 percent; lime, 3.15 percent; iron oxides, 1.80 percent; insoluble ("stone"), 3.40 percent; and loss on ignition, 49.20 percent. This analysis corresponds to a magnesium carbonate content of 89 percent.

Imports of magnesite into the United States are occasionally reported in the official statistics as coming from Italy, but it is believed that they consist exclusively of Austrian magnesite that happened to be invoiced at Trieste, which became an Italian port after the World War.

*Manchuria.*⁸—Production of magnesite in Manchuria first rose above 10,000 tons in 1924 and did not rise above 35,000 tons until 1931, but since then it has increased rapidly to 134,220 tons in 1935. Originally most of the Manchurian magnesite was consumed in Japan, but in recent years exports have been made to Europe. About 2,000 tons of magnesite products per year, mostly clinker, have been used for making brick at the iron works of Anshan and Pen-hsi-hu, near Mukden. In addition, about 3,000 tons of caustic magnesite were used in 1935 for making sord cement. Seven factories for treating Manchurian magnesite have been built since 1918; all are between Mukden and Dairen. The oldest and by far the largest is that of the South Manchurian Mining Co. (Nan-man-Kōgyō-Kaisha), which produces about 2,500 tons of clinker and 250 tons of caustic magnesite per month—more than twice as much as all the other plants combined.

Several sizes of dead-burned magnesite are produced. That in lumps, 1 to 3 cm in diameter sells for about 50 yen per ton at the port of Ying-Kou, 22 km west of Ta-shih-chiao. Caustic magnesite, mostly powdered, is cheaper (about 41 yen per ton at the same port). Probably 90 percent of the Manchurian magnesite is used for refractory purposes, after being dead burned in Manchuria, Japan, or elsewhere.

Prior to 1936 none of the Manchurian magnesite had been used for making metallic magnesium. However, in 1935 substantial tonnage of metal was made in Korea from Korean magnesite, and preparations have been made for utilizing Manchurian magnesite for this purpose at the plant in the city of Ube, Yamaguchi Prefecture, western Japan, where several hundred tons of magnesium metal have been made from bitters obtained from nearby salt works.

The Manchurian magnesite deposits are among the largest in the world. One group on the east side of Ta-shih-chiao occupies an area 50 km long (from east to west) and 6 km wide and contains 5,000 million tons. The magnesite is associated with pre-Cambrian dolomites and schists that generally strike east to west and dip to the south. These deposits, controlled by the South Manchurian Railway

⁸Niinomy, K., Recent Developments in Magnesite Industry of Manchoukuo: Econ. Geol., vol. 31, no. 7, November 1936, pp. 767-769; Magnesite Deposits of Manchuria; Econ. Geol., vol. 20, 1925, pp. 25-53.

Co., are now managed by the Manchu Mining Development Co. (Manshu-Kozan-Kaihatsu-Kaisha).

Norway.—A Bergen firm is reported ⁹ to have obtained a lease for working on a royalty basis magnesite deposits recently discovered at Hegvestad.

South Africa.—High-grade magnesite, mined in the Barberton and Lydenburg districts, is used locally for flooring cements; the carbon dioxide is recovered and sold in cylinders as compressed gas. An average analysis shows: MgCO_3 , 97.37 percent; CaCO_3 , 0.85 percent; SiO_2 , 1.20 percent; and Fe_2O_3 , 0.48 percent. Research has been in progress for a year or two with a view to making magnesite brick from this material.

Turkey.¹⁰—Large deposits of high-grade magnesite are reported in the Denizli and Eskishehir districts; in the latter area the magnesite runs up to 97.4 percent MgCO_3 and is quite low in iron. Following a reduction in railway transportation costs a private enterprise began mining in the Eskishehir district and expected to make exports in 1936. German buyers were negotiating for the product at 9 to 9½ Turkish pounds a ton, which was considered rather a high price. It was believed that by utilizing idle cement kilns in Istanbul caustic calcined magnesite could be offered locally at 70 to 80 shillings.

Yugoslavia.—High-grade magnesite, 96 to 99 percent pure, is reported to have been discovered in the Takovo district of the Danube Banovina, according to a brief statement from Consul Charles S. Reed, second, Belgrade. Consul Reed Paige Clark reports that Yugoslavia has five important magnesite deposits and eight mines. Nine-tenths of the total supply lies in the Valjevo-Cacak-Pozega-Nova Varos-Priboj-Visegrad-Bajina Basta territory. The largest section of country south of Valjevo is served by a narrow-gage railway. Magnesite is exported crude, ground or unground, and sintered. A representative sample of crude ore carries 98 percent MgCO_3 and one calcined ore, 90 to 95 percent MgO . The ore contains little silica and alumina. Exports in 1934 were 1,333 short tons of lump magnesite and 9,324 tons of ground and calcined magnesite. During the first half of 1935 exporting rates were much higher.

DOLOMITE

Dolomite (magnesium-calcium carbonate) is a source of most of the basic carbonate used in "85-percent magnesia" pipe and boiler coverings and competes with magnesite and natural brines as a source of magnesium salts for medicinal and technical use. Dead-burned dolomite is many times as important as dead-burned magnesite as a steel-works refractory (at least as regards tonnage consumed), and dolomitic lime is used in making sulphite pulp and for sundry other purposes that formerly consumed substantial tonnages of magnesite. Raw dolomite is used for patching open-hearth furnace bottoms and for making carbon dioxide, often with Epsom salts as a joint product.

In 1936 sales of dead-burned dolomite rose to 557,000 tons valued at \$4,693,000 (preliminary figures) compared with 455,258 short tons valued at \$3,785,834 in 1935, an increase of 22 percent in quantity and 24 percent in value. In 1935, 4,965 tons of lime were sold to magnesia works and paper mills used 344,531 tons of lime, most of

⁹ Chemistry and Industry (London), Industrial Notes from Abroad: Vol. 56, no. 3, Jan. 16, 1937, p. 63.

¹⁰ Data from Acting Commercial Attaché John A. Embry, Istanbul, Foreign Met. and Min. Circ. 4, May 15, 1936, p. 27; no. 5, June 15, 1936, pp. 27-28.

which was dolomitic. Detailed figures as to use of lime and data as to the distribution of raw stone are given in the Lime and Stone chapters. For many uses dolomitic limes or high-magnesium limestones are more effective than high-calcium lime or stone, but it is impossible to draw even an approximately accurate distinction between the uses in which the magnesia content plays a dominant or important role. It seems likely that in many instances a magnesian limestone may be rejected in favor of a high-calcium lime stone from another source, or vice versa, for some reason other than the lime-magnesia ratio. More intelligent analysis might show that the underlying cause of such rejection is poor grading of the stone from a local quarry or some constituent impurity. Accordingly there is no statistical approach to the problem of when a magnesia content represents an advantage and when a disadvantage.

Imports of dead-burned dolomite have been reported separately since 1930; these comprise principally the so-called magnesitic dolomite dead burned in Canada for steel-works refractories. In 1936, after the reciprocal treaty had been concluded between the two countries, the classification was modified to read "dead-burned basic refractory material containing 6 percent or more of lime and consisting chiefly of magnesia and lime", and imports rose to 13,928 short tons valued at \$349,678 compared with 7,519 tons valued at \$189,714 in 1935. Statistics are available only on the value of this material in Quebec. According to the preliminary report of the Dominion Bureau of Statistics, the Canadian output of magnesitic dolomite was valued at \$769,176 in 1936, a 58-percent increase over the \$486,084 in 1935.

MAGNESIUM SALTS

Improved technique for handling magnesium precipitates, especially from dilute solutions, has made possible the commercial recovery not only of technical carbonate but of refractories and other moderately low priced magnesia products from natural brines and bitterns and even from raw ocean water. As a result, the potential importance of natural magnesium salts has increased enormously.

DOMESTIC PRODUCTION

The total quantity of natural magnesium salts (sulphate, chloride, and carbonate from brine wells and sea water) sold or used in the United States, as reported by producers, increased in 1936 to 127,682,793 pounds valued at \$1,629,725 compared with 109,601,855 pounds valued at \$1,286,804 in 1935. Magnesium sulphate still leads the magnesium salts in quantity produced, but separate figures for this salt and for the chloride and carbonate may not be published.

The Dow Chemical Co., Midland, Mich, produced both magnesium sulphate and chloride from its natural brines. The California Chemical Co., operating at San Francisco, recovered magnesium chloride from bittern waters. Magnesium carbonate was produced from sea water by the Marine Chemicals Co., Ltd., South San Francisco, Calif., and the Plant Rubber & Asbestos Works (537 Brannan Street, San Francisco, Calif.); also from the salt wells of the Morton Salt Co. (208 West Washington Street, Chicago, Ill.), in Manistee County, Mich. C. A. Kearney (1208 Post Street, Seattle, Wash.), reported production of magnesium sulphate from natural deposits of epsomite near Oroville, Okanogan County, Wash.

IMPORTS

German shipments of magnesium chloride to the United States have dwindled to insignificant proportions, and notwithstanding a notable recovery in 1936 shipments of magnesium sulphate likewise have diminished greatly during the last 15 years. On the other hand, imports of calcined magnesia and precipitated carbonate, mostly of British origin, have increased, as shown in the following table.

*Magnesium compounds imported for consumption in the United States, 1920-36*¹

Year	Magnesium chloride (hydrated and anhydrous)		Magnesium sulphate (Epsom salts)		Calcined magnesia		Carbonate, precipitated		Magnesium silicofluoride or fluosilicate

Further increases marked production of most of the important abrasive materials in 1936. Compared with 1935 there were substantial increases in the output of ground sand and sandstone, pumice and pumicite, oilstones and related products, garnet, and emery. Moderate gains were also reported in the production of tripoli and millstones. These gains, however, were offset by decreases in the production of quartz and grindstones and pulpstones. The aggregate value of the abrasive materials produced in 1936, exclusive of diatomite for which the Bureau of Mines is not at liberty to publish annual figures, was \$11,186,941 compared with \$11,196,424 in 1935.

Abrasive materials are used extensively in the manufacture of numerous products. The quantities used are related directly to the production of various commodities; hence the volume of production is to a considerable extent an indicator of industrial activity. The following table of salient statistics therefore presents not only trends in activity of each abrasive material but also to some degree those of the industries in which the abrasives are employed.

Some commodities included in this chapter also have important nonabrasive uses. For example, the quantity of diatomite now used as an abrasive is relatively small compared with the quantity formerly so used. It seems desirable, however, to continue to include such commodities in the annual chapters of this series for purposes of comparison until the minerals in this diverse group are reclassified. On the other hand, it should be noted that figures covering the quantities of sundry materials used for abrasives and mentioned later under the caption "Miscellaneous abrasive materials" are not included in this chapter.

Diatomite.—Diatomite is still used as a mild abrasive in metal polishes, scouring and cleansing soaps and compounds, dentifrices and nail polishes, although its principal outlets, in the insulation, filtering, and absorption-agent fields, are nonabrasive.

The principal centers of diatomite production in the United States are now the Western States; four of the seven States that produced diatomite in 1936—California, Oregon, Washington, and Nevada—were in that region, and the remaining three—New York, New Jersey, and Florida—were in the East. There were 18 producing companies in the United States in 1936; all but 3 of them were in the western area.

California, with its immense deposits, was the chief source of the diatomite produced in the United States in 1936, as it has been in recent years; eight companies operated on deposits in central and southwestern California—three at Lompoc, Santa Barbara County; two at Waleria and one at Palos Verdes, Los Angeles County; and one each at Mendota, Fresno County, and Bradley, Monterey County.

In Nevada three producers were operating at widely scattered localities—one near Virginia City, Storey County, in the west-central part of the State; another near Tonopah, Esmeralda County, in the southwestern part of Nevada; and the third near Carlin, Elko County, in the northeastern corner of the State.

The three producing companies in Washington are reported to have operated deposits in 1936 in Kittitas, Grant, and Adams Counties.

Only one company was operating in each of the other States—Oregon, New York, New Jersey, and Florida.

*Diatomite sold or used by producers in the United States, 1930-35*¹

Year	Short tons	Value	Year	Short tons	Value

¹ Bureau of Mines not at liberty to publish annual figures.

The trend of diatomite production in immediate predepression years was upward. (See figure 100.) Since 1929, the trend, as indicated by 3-year averages, appears to have been downward, but annual production figures, which the Bureau of Mines is not at liberty to publish, show a marked recovery in the production of diatomite from the depression low in 1932.

FIGURE 100.—Trends in production of diatomite, tripoli, pumice and pumicite, quartz, and ground sand and sandstone, 1919-36.

The companies reporting production and sales of diatomite in the United States in 1936, with locations of the deposits from which it was obtained, were as follows:

Adirondack Diatomaceous Earth Co., Keene, N. H. Deposit near Poland, Herkimer County, N. Y.

American Diatomite Corporation. Deposit and office at Clermont, Lake County, Fla.

Diatomaceous Earth Corporation of America, 1325 Pico Avenue, Long Beach, Calif. Deposit at Waleria, Los Angeles County, Calif.

The Dicalite Co., 756 South Broadway, Los Angeles, Calif. Deposit at Waleria, Los Angeles County, Calif.

The Electro-Silicon Co., 130 Cedar Street, New York, N. Y. Deposit at Virginia City, Storey County, Nev.

Johns-Manville Products Corporation, 22 East Fortieth Street, New York, N. Y. Deposit at Lompoc, Santa Barbara County, Calif.

Kittitas Diatomite Co., Washington National Bank Building, Ellensburg, Wash. Deposit at Kittitas, Kittitas County, Wash.

Langlois Bros., 717 South San Pedro Street, Los Angeles, Calif. Deposit near Tonopah in Esmeralda County, Nev.

Marcum, J. G., Netcong, N. J. Deposit near Stanhope, Sussex County, N. J. Mineral Products Manufacturing Co., 1735 Ventura Avenue, Fresno, Calif. Deposit at Mendota, Fresno County, Calif.

National Silica Products Co., 1201 Bryant Street, Palo Alto, Calif. Deposit at Lompoc, Santa Barbara County, Calif.

The Oromite Co., American Bank Building, Portland Oreg. Deposit at Terrebonne, Deschutes County, Oreg. (Successor to the Atomite Products Co.)

Pacatome, Ltd., Bradley, Calif. Deposit near Bradley, Monterey County, Calif.

The Paraffine Cos., Inc., 475 Brannan Street, San Francisco, Calif. Deposit near Lompoc, Santa Barbara County, Calif.

Raylite Aggregates, Inc., 1302 Park Central Building, Los Angeles, Calif. Deposit at Palos Verdes, Los Angeles County, Calif.

State Products Co., 315 South Fourth Avenue, Yakima, Wash. Deposits at Quincy, Grant County; Othello, Adams County; and in Kittitas County, Wash.

Tri-O-Lite Products Co. Deposit and office at Carlin, Elko County, Nev.

Webley, E. J. Deposit and office at Quincy, Grant County, Wash.

Although diatomite occurs in nearly every country in the world it has been produced in only 23 countries in recent years. The United States is by far the largest producer, but considerable quantities are produced in Algeria, Australia, Denmark, France, Germany, Hungary, Italy, Japan, Northern Ireland, Portugal, and Sweden. No 1936 production figures are yet available. The largest foreign producing countries in 1935 were Denmark with 47,200 long tons of an impure diatomaceous earth called "molererde" and Algeria with 11,200 tons of diatomite.

Tripoli.—The materials grouped under this heading include certain naturally occurring and extremely fine-grained forms of silica, such as tripoli and rottenstone. Deposits of tripoli occur in southeastern,¹ central, and western United States, but the tripoli industry has centered largely in the Missouri-Oklahoma and Illinois fields. Rottenstone is produced only in Pennsylvania.

The tripoli industry of the United States is small; the tonnage produced annually in the post-war years has ranged from 12,000 to 40,000 short tons. In 1936, 28,487 short tons of tripoli and related products were produced in Arkansas, California, Illinois, Missouri, Oklahoma, and Pennsylvania. The Missouri-Oklahoma and Illinois fields were

Tripoli (including Pennsylvania rottenstone) sold or used by producers in the United States, 1932-36

² No sales of crude reported in 1934.

³ Crickmay, C. W., *Tripoli Deposits of Georgia*: Georgia Dept. Forestry and Geol. Devel., Div. of Geol. Inf. Circ. 9, January 1937, 8 pp.

the principal producing areas. The following table gives production data for tripoli for 1932-36. The tonnage for 1919-36 is shown in figure 100.

The domestic production of tripoli is used principally for abrasives, fillers, and concrete admixture and the production of rottenstone for abrasives and fillers. In 1936 nearly 60 percent of the combined production of these two materials went into abrasive uses, and 11 percent was used as fillers. Over 7 percent of the tripoli produced was used in concrete admixtures. The following table presents statistics on the quantity and value of tripoli and rottenstone sold by producers and classified according to uses, as compiled from data furnished by the producers.

Tripoli sold or used by producers in the United States in 1936, by uses

² A producer reporting more than 1 use is counted only once in arriving at total.

The companies reporting production and sales of tripoli (including Pennsylvania rottenstone) in the United States in 1936, with locations of the deposits from which the material was obtained, were as follows:

Barnsdall Tripoli Corporation, Seneca, Mo. Deposits at Seneca, Newton County, Mo., and in Ottawa County, Okla., near Seneca, Mo.

Corona Products, Inc. Deposit and office at Rogers, Benton County, Ark.

Friend, D. N., and Wheeler, H. R., Joplin, Mo. Deposit near Peoria, Ottawa County, Okla.

Independent Gravel Co., 220½ West Fourth Street, Joplin, Mo. Deposits at Racine, Newton County, Mo., and in Ottawa County, Okla., near Seneca, Mo.

Olive Branch Minerals Co., 333 Third Street, Cairo, Ill. Deposit at Olive Branch, Alexander County, Ill.

Ozark Minerals Co., 807½ Washington Avenue, Cairo, Ill. Deposit at Elco, Alexander County, Ill.

Penn Paint & Filler Co., Antes Fort, Pa. Deposit near Oriole, Lycoming County, Pa.

Western Talc Co., 1901 East Slauson Avenue, Los Angeles, Calif. Deposit near Barstow, San Bernardino County, Calif.

Quartz.—Quartz is the abrasive agent in some kinds of sandpaper, soaps, and scouring compounds, metal polishes, and safety matches. The material is obtained from pegmatite dikes, veins, or beds of quartzite. In 1936 the production of quartz from these sources in the United States amounted to 12,986 short tons valued at \$96,592, a marked decrease in tonnage and value compared with 1935 and a still further decline from the recent peak year of 1934 when 18,293 tons valued at \$129,965 were sold. Of the total production in 1936, about 48 percent was sold by the producers as crude or crushed quartz and 52 percent as ground quartz. Arizona, California, New Jersey, New York,

Ohio, and Tennessee have been constant producers in recent years. In addition to these States, Maryland, Missouri, North Carolina, Wisconsin, and Virginia have produced quartz 1 or more years.

Data covering sales of crude and ground quartz from 1932 to 1936 and sales of crude, crushed, and ground quartz by States from 1932 to 1936 are shown in the two following tables.

Quartz sold or used by producers in the United States, 1932-36

³ 1934: Arizona, California, Missouri, New Jersey, New York, North Carolina, Ohio, Tennessee, and Virginia; 1935: Arizona, Missouri, New Jersey, New York, North Carolina, Ohio, and Tennessee; 1936: Arizona, California, New Jersey, New York, Ohio, and Tennessee.

The trend in the production of quartz for the past 9 years for which statistics are available is shown in figure 100.

A list of some recent producers and sellers of crude quartz follows:

Carolina China Clay Co., Penland, N. C.
 Carolina Minerals Co., Inc., Spruce Pine, N. C.
 Consolidated Feldspar Corporation, Trenton, N. J.
 Day Quartz Co., Sykesville, Md.
 H. O. DeBeck, Burnsville, N. C.
 Harford Talc & Quartz Co., P. O. Box 63, Towson, Md.
 Kingman Feldspar Co., Kingman, Ariz.
 Ohio Quartz Products Corporation, Jackson, Ohio.
 J. C. Pitman Estate, Penland, N. C.
 C. F. Wolfradt, 319 South 8th Street, Alhambra, Calif.

A list of producers of crushed quartz follows:

Consolidated Feldspar Corporation, Trenton, N. J.
 Harford Talc & Quartz Co., P. O. Box 63, Towson, Md.
 Ohio Quartz Products Corporation, Jackson, Ohio.
 Tennessee Mineral Products Corporation, Spruce Pine, N. C.

A list of manufacturers of ground quartz follows:

Charlotte Chemical Laboratories, Inc., Charlotte, N. C.
Consolidated Feldspar Corporation, Trenton, N. J.
Eureka Flint & Spar Co., Trenton, N. J.
Harford Tale & Quartz Co., P. O. Box 63, Towson, Md.
Tennessee Mineral Products Corporation, Spruce Pine, N. C.

Ground sand and sandstone.—Ground sand and sandstone are used as abrasives in various cleaning and scouring compounds; a third to a fourth of the total domestic production now enters abrasive compounds. The material so used is sold by companies producing glass sand and other special silica sands largely in the eastern and north-central United States; Illinois, New Jersey, Ohio, and Pennsylvania are among the largest producers.

The following tables give production data from 1932 to 1936 both for the United States as a whole and for such States as can be shown.

*Ground sand and sandstone sold or used by producers in the United States, 1932-36*¹

The trends in the production of ground sand and sandstone since 1919 are shown in figure 100.

The quantities of ground sand and sandstone sold for different uses and the values of the quantities so used, together with the average values per ton for each use are shown in the following table. These data, available for the first time, cover 69 percent of the industry.

*Ground sand and sandstone sold or used by producers in the United States in 1936, by uses*¹

	Short tons	Value	
		Total	Average value per ton
Foundry.....	26,310	\$143,733	\$5.46
Pottery, porcelain, and tile.....	109,644	848,523	7.74
Enamel.....	13,220	110,454	5.75

Other abrasive use.....	10,874	48,702	4.48
Filler.....	9,325	49,825	5.34
Other.....	14,052	74,925	5.33
	247,482	1,542,476	6.23

¹ Data represent 69 percent of the industry.

The following companies reported production of ground sand and sandstone in 1936:

Central Silica Co., Zanesville, Ohio.
 Cheshire White Quartz Sand Co., Cheshire, Mass.
 Del Monte Properties Co., 401 Crocker Building, San Francisco, Calif.
 Michigan Quartz Silica Co., Milwaukee, Wis.
 Minnesota Mining & Manufacturing Co., St. Paul, Minn.
 National Pulverizing Co., Millville, N. J.
 National Silica Co., Oregon, Ill.
 National Silica Works, Berkeley Springs, W. Va.
 New Jersey Pulverizing Co., 205 West Thirty-fourth Street, New York, N. Y.
 Ottawa Silica Co., Box 437, Ottawa, Ill.
 Pennsylvania Glass Sand Corporation, Lewistown, Pa. (Grinds in New Jersey, Pennsylvania, and West Virginia.)
 Pioneer Silica Products Co., R. F. D. 3, Pacific, Mo.
 Potters Mining & Milling Co., East Liverpool, Ohio.
 Shenandoah Silica Co., P. O. Box 266, Trenton, N. J.
 Standard Flint & Spar Corporation, Trenton, N. J.
 Standard Sanitary Manufacturing Co., Campo, Calif.
 Standard Silica Co., Box 407, Ottawa, Ill.
 Toledo Vitrified Brick Co., 1220 Madison Avenue, Toledo, Ohio.
 Wedron Silica Co., 38 South Dearborn Street, Chicago, Ill.
 White Rock Silica Co. of Wisconsin, Inc., Browntown, Wis.

Abrasive sand.—The production of sand in the United States for abrasive purposes depends largely upon conditions in the dimension-stone and plate-glass industries, and production in recent years has followed the general industrial trend—a peak of 1,636,464 short tons in 1929, a low of 419,691 tons in 1932, and recovery to 816,540 tons in 1935, with a total value of \$1,198,653, and an average value of \$1.47 a ton. Preliminary estimates indicate that of a total commercial production of sand and gravel of 119,660,000 tons in the United States in 1936 there were 960,000 tons of sand used for grinding and polishing having an average value of \$1.38 and a total value of \$1,320,000, a considerable increase over 1935. The relationships of abrasive sand to the rest of the sand and gravel industry are shown in the chapter on Sand and Gravel.

SPECIAL SILICA STONE PRODUCTS

Grindstones and pulpstones.—In 1936 most of the production of natural grindstones and pulpstones came from northeastern Ohio and western West Virginia; smaller quantities came from Skagit and Pierce

Counties, Wash. Both the quantity and value of sales of grindstones decreased compared with 1935. Sales of pulpstones in 1936 decreased in quantity but increased slightly in value.

The following table shows the sale of these materials from 1932 to 1936:

Grindstones and pulpstones sold by producers in the United States, 1932-36

Year	Grindstones		Pulpstones		
	Short tons	Value	Pieces	Short tons	Value
1932.....	6,001	\$158,506	483	1,667	\$88,874
1933.....	11,197	298,174	855	2,979	146,076
1934.....	9,781	285,603	760	2,849	177,631
1935.....	11,476	342,864	948	3,111	162,514
1936.....	10,703	334,363	685	2,472	163,634

The general downward post-war trend in output of grindstones from 1920 to 1932 was probably due to substitutions of manufactured abrasive wheels for natural grindstones. (See fig. 101.) Since

FIGURE 101.—Trends in production of grindstones and pulpstones in the United States, 1919-36.

1932, however, the production of grindstones has recovered moderately. Figure 101 also indicates that the production of pulpstones has fluctuated only slightly since 1919.

The companies reporting production of grindstones and pulpstones for commercial purposes in the United States in 1936, with locations of the quarries from which the stone was obtained, are as follows:

Briar Hill Stone Co. (grindstones). Quarry and office at Glenmont, Holmes County, Ohio.

C. & M. Quarries Co., Marietta, Ohio (pulpstones). Quarry at St. Marys, Pleasants County, W. Va.

Cleveland Quarries Co., Cleveland, Ohio (grindstones). Quarries at Amherst, Lorain County, Ohio; at Berea, Cuyahoga County, Ohio; and at Marietta, Washington County, Ohio.

Constitution Stone Co., Constitution, Ohio (grindstones and pulpstones). Quarries at Constitution, Washington County, Ohio; at Crow Summit, Jackson County, W. Va.

General Stone Co., Amherst, Ohio (pulpstones). Quarry at Opekiska, Monongalia County, W. Va.

Hall Grindstone Co. (grindstones). Quarry and office at Marietta, Washington County, Ohio.

Mount Pisbia Stone Co., Elyria, Ohio (grindstones). Quarry at Layland, Coshocton County, Ohio.

Nicholl Stone Co., Lorain, Ohio (grindstones). Quarry at Kipton, Lorain County, Ohio.

Ohio Valley Stone Co. (grindstones). Quarry and office at Marietta, Washington County, Ohio.

H. P. Scheel Co., Rockport, Wash. Quarry and office at Rockport, Skagit County, Wash.

Smallwood-Low Stone Co., Fairmont, W. Va. (pulpstones). Quarry in Monongalia County near Fairmont, W. Va.

Smallwood Stone Co., Union Trust Building, Cleveland, Ohio (pulpstones). Quarry at Opekiska, Monongalia County, W. Va.

Walker Cut Stone Co., Tacoma, Wash. (pulpstones). Quarry at Wilkeson, Pierce County, Wash.

West Virginia Pulpstone Corporation, Builders Exchange Building, Cleveland, Ohio (pulpstones). Quarry at Morgantown, Monongalia County, W. Va.

Oilstones and related products.—Sales of oilstones and related products of domestic origin were much greater in 1936 than in 1935 both in quantity and value; being greater in quantity than in any year since 1929 and in value since 1930. The oilstones sold were manufactured from novaculite quarried in Arkansas; the scythestones and whetstones were made from sandstone from Ohio and Indiana and schist from New Hampshire; and fine-grain sandstones quarried in Indiana and Ohio were used as raw materials for the manufacture of rubbing stones. There were two new producers in this group in 1936—the Bracher Agate & Abrasive Co., Summit, N. J., which manufactured oilstones from Arkansas novaculite, and Gil H. Wootten, Hot Springs, Ark., who produced oilstones in Garland County, Ark.

Oilstones and other whetstones, hones, scythestones, and rubbing stones sold by producers in the United States, 1932–36

Year	Short tons	Value	Year	Short tons	Value
1932	331	\$63,960	1935	439	\$105,589
1933	587	96,597	1936	752	121,196
1934	396	94,419			

The manufacturers of oilstones and other whetstones, scythestones, and rubbing stones from natural stone in 1936 with the sources of their raw materials, are as follows:

American Rubbing Stone Co., Cincinnati, Ohio (rubbing stones). Quarry at Floyds Knobs, Floyd County, Ind.

Bracher Agate & Abrasive Co., Summit, N. J. (oilstones). Manufactures stone obtained from Arkansas.

Cleveland Quarries Co., Cleveland, Ohio (scythestones, lathe stones, and holystones). Quarries at Amherst, Lorain County, Ohio, and at Berea, Cuyahoga County, Ohio.

Garland Whetstone & Kaolin Co., John C. Wolf, Hot Springs, Ark. (Produces rough stone, in Garland County, for oilstones, some of which is shipped abroad, and some of which is sold to manufacturers in this country.)

Lewis Whetstone Co., W. E. Lewis, Hot Springs, Ark. (Produces rough stone, in Garland County for oilstones, most of which is shipped to Germany.)

Norton Pike Co., Littleton, N. H. (oilstones, whetstones, and scythestones). Production from Pike, Grafton County, N. H.; Hot Springs, Garland County, Ark.; McDermott, Scioto County, Ohio; and West Baden, Orange County, Ind. (Quarries owned are in Arkansas and New Hampshire. Purchases stone from Ohio and Indiana.)

West Baden Whetstone Co. Quarries at West Baden, Ind. (Sells this stone to Norton Pike Co. Buys Arkansas and Ohio stone and manufactures it.)
Wootten, Gil H., Hot Springs, Ark. (oilstones). Produces rough stones in Garland County.

Millstones.—The downward trend in the value of natural millstones produced in the United States, which began in 1935 after 2 years of recovery from the low point of the depression in 1932, was stopped in 1936, and sales, which in 1935 had dropped to a value of \$9,530, rose to \$10,609 in 1936. The number of producers, which had reached 11 in 1935, is reported to have decreased to 9. Sales were confined to two States, New York with six producers and Virginia with only three. Production in 1936 was confined to millstones of conglomeratic and quartzitic types. Quarries yielding these types are known to have been in operation at two localities in the eastern United States—Ulster County, N. Y. (yielding the "Esopus" stone from the Shawangunk conglomerate), and Brush Mountain, Montgomery County, Va. (furnishing the "Brush Mountain" stone—a fine-grained quartzite). None of the granitic type of millstones, such as have come in recent years from Salisbury, Rowan County, N. C., are known to have been produced in 1936.

The following table presents annual production data for natural millstones and related products both for the United States as a whole and for the various States from 1932 to 1936.

Value of millstones, chasers, and dragstones sold by producers in the United States, 1932-36

Year	New York		Other States ¹		Total	
	Producers	Value	Producers	Value	Producers	Value
1932.....	5	\$1,850	2	\$2,600	7	\$4,450
1933.....	7	5,187	2	3,200	9	8,387
1934.....	5	3,381	3	6,720	8	10,101
1935.....	8	4,645	3	4,885	11	9,530
1936.....	6	5,458	3	5,151	9	10,609

¹ 1932-35: North Carolina and Virginia; 1936: Virginia.

The following are names and addresses of the producers who reported sales of millstones and chasers of their own manufacture in the United States in 1936; the raw material from which the stones were made was obtained from Ulster County, N. Y.; and Montgomery County, Va.

Addis, Wilson C., Stone Co., R. D. 2, Laurence, Harry, Accord, N. Y.
 Kerhonkson, N. Y. Olinger, P. L. (Virginia Abrasive Co.),
 Blacksburg, Va.
 Coddington, George, Accord, N. Y.
 Coddington, Oscar, Accord, N. Y. Shealor, J. Fred (Virginia Millstone
 Decker, Floyd, Kerhonkson, N. Y. Co.), R. D. 2, Blacksburg, Va.
 Esopus Millstone Co., High Falls, N. Y. Snider, R. E., Cambria, Va.

Flint lining and grinding pebbles.—In certain American mineral industries that require a ground product with a minimum iron content, there is a continuing but moderate demand for noncontaminating grinding materials, such as flint lining and grinding pebbles. In recent years this demand has been met by two producers in the central and western United States. In 1936 there was only one producer of these materials—the Jasper Stone Co., Sioux City, Iowa—which

reported the sale of cut cubes and tube-mill liners made from quartzite quarried near Jasper, Rock County, Minn. This company reported better economic conditions in 1936 and a large increase in output. No beach pebbles from the Pacific Ocean front in San Diego County, Calif., were marketed in 1936, as in recent past years, as the business formerly conducted by John T. Momand was discontinued.

NATURAL SILICATE ABRASIVES

Pumice and pumicite.—Although commercial deposits of pumice and pumicite occur in many parts of the central and western United States, pumice—a cellular glassy lava was produced in 1936 only in California and New Mexico; and pumicite—finely divided glassy particles ejected during volcanic eruptions, known also as volcanic ash and volcanic dust—was produced in 1936 in California, Oklahoma, Kansas, and Nebraska. The pumice deposit near Grants, N. Mex., is said to yield a product similar to the Italian pumice.

Sales of pumice and pumicite in 1936 were considerably larger in both quantity and value than in 1935. The following table shows the quantity and value of pumice and pumicite sold or used by producers for 1932-36. The next table shows sales according to uses. Most of the material was used for cleansing and scouring compounds and hand soaps. Sales for concrete admixture and concrete aggregate were the second most important outlet, and showed a large increase over 1935. Sales for acoustic plaster were also larger than in 1935.

The trend in the production of pumice and pumicite during post-war years is shown in figure 100.

Pumice and pumicite sold or used by producers in the United States, 1932-36

² Revised figures.

³ 1935: Includes material used in asphalt, grading roads, chicken litter, filtering, manufacture of cement, rock gardens and landscaping, floor sweep, insecticide, and some unspecified uses; 1936: Includes material used in asphalt, grading roads, chicken litter, filtering, heat or cold insulating medium, other abrasive uses (unspecified), paints, floor sweep, and some unspecified uses.

The companies reporting production and sales of pumice and pumicite in the United States in 1936, with locations of the deposits from which the materials were obtained, were as follows:

Barnsdall Tripoli Corporation, Seneca, Mo. Deposit at Grants, Valencia County, N. Mex.

Basalt Rock Co., Inc. Deposit and office at Napa, Napa County, Calif.

Brown, Charles. Deposit and office at Shoshone, Inyo County, Calif.

Calaveras Cement Co., 315 Montgomery Street, San Francisco, Calif. Deposit at Wallace, Calaveras County, Calif.

California Quarries Corporation, 1300 Quinby Building, Los Angeles, Calif. Deposit in Mono County near Laws, Calif.

Chamberlain Co., Inc., 2550 East Ninth Street, Los Angeles, Calif. Deposit near Calipatria, Imperial County, Calif.

The Cudahy Packing Co., 221 North La Salle Street, Chicago, Ill. Deposits at Fowler, Meade County, Kans., and at Saltdale, Kern County, Calif.

The Davidson Pumice Co., Norton, Kans. Deposits at Calvert, Norton County, Meade, Meade County, and Natoma, Osborne County, Kans.

Dodson Concrete Board Co., 1463 Barwise Avenue, Wichita, Kans. Deposit at Wilson, Ellsworth County, Kans.

Friant Pumice Co., 816 Pacific Southwest Building, Fresno, Calif. Deposit in Madera County near Friant (Fresno County), Calif. (Successor to Bennett & Jourdan.)

La Rue Axtell Pumice Co., Eustis, Nebr. Deposits at Eustis, Frontier County, and Ingham, Lincoln County, Nebr.

Little Lake Pumice Co., 1204 South Monterey Street, Alhambra, Calif. Deposit near Little Lake, Inyo County, Calif.

Mid-Co Products Co., 238 Railway Exchange Building, Kansas City, Mo. Deposits at Meade, Meade County, and in Grant County near Satanta (Haskell County), Kans., and near Gate, Beaver County, Okla.

Pearl Pumice Quarries, Box 565, Monticello Way, Napa, Calif. Deposit near Napa, Napa County, Calif.

Pumicite Co., 4025 Clara Avenue, St. Louis, Mo. Deposit at Fowler, Meade County, Kans.

Red Eagle Placer Mining Claim (M. L. Francis), R. F. D., Creston, Calif. Deposit near Creston, San Luis Obispo County, Calif.

Tonopah & Tidewater Railway, 510 West Sixth Street, Los Angeles, Calif. Deposit at Shoshone, Inyo County, Calif.

Garnet.—The industrial recovery in the United States in recent years has resulted in a greater demand for garnet as an industrial abrasive. Production in 1936—3,820 tons with a value of \$315,913—was nearly double the output and more than double the value in 1932,

the low point in abrasive-garnet production. There were increases of 25 percent in quantity and 23 percent in value in 1936 over 1935. Garnet was produced and marketed in 1936 in New York, New Hampshire, and North Carolina. Increased sales due to better business conditions were reported in both New York and New Hampshire. New York, which produced a grade of abrasive garnet recognized as the world standard, was the leading shipper. The garnet produced in North Carolina was recovered as a byproduct of kyanite operations. Production by individual States cannot be given because there were less than three producers in each.

Little interest was taken in 1936 in other possible garnet deposits in the United States because the productive capacity of existing plants exceeded trade demands.

Most of the garnet sold in 1936 was for use in the manufacture of garnet paper and cloth for the woodworking and shoe-manufacturing industries.

Prices of garnet concentrates were unchanged throughout 1936 from those at the end of 1935, according to quotations in the Engineering and Mining Journal (Metal and Mineral Markets). Adirondack (New York) garnet concentrates, f. o. b. mines, were constant at \$85 a ton, and New Hampshire garnet concentrates, f. o. b. mines, remained at \$30 a ton. Quotations for Spanish garnet, c. i. f. port of entry, were \$60 a ton throughout 1936.

The following table shows the quantity and value of abrasive garnet sold or used by the producers since 1932.

Abrasive garnet sold or used by producers in the United States, 1932-36

Year	Short tons	Value	Year	Short tons	Value
1932.....	1,950	\$147,350	1935.....	3,060	\$256,520
1933.....	2,794	224,717	1936.....	3,820	315,913
1934.....	2,591	214,815			

The companies reporting sales of garnet in the United States in 1936, with locations of the deposits from which the garnet was obtained, are as follows:

Barton Mines Corporation, North Creek, Warren County, N. Y. Deposit on Gore Mountain, Warren County, N. Y.

Celo Mines, Inc., Burnsville, N. C. Recovered as a byproduct from kyanite mines near Burnsville, Yancey County, N. C.

Davenport Garnet Co., South Danbury, N. H. Deposit near Wilnot, Merrimack County, N. H.

Warren County Garnet Mills, Inc., 149 Orange Street, Newark, N. J. Deposit near Riparius, Warren County, N. Y.

Trends in production of garnet and artificial abrasives—silicon carbide and aluminum oxide—since 1920 compared with the Federal Reserve Board index of industrial production are shown in figure 102. The index of production of artificial abrasives has fluctuated about the index of industrial production but with increasing amplitude, whereas from about 1925 until 1932 the index of garnet sales fell farther below the industrial index. Since 1932 sales of garnet have responded to the industrial recovery, and the trend of the index of garnet sales has been upward.

NATURAL ALUMINA ABRASIVES

Corundum.—Corundum has not been mined in the United States since 1918, and so far as is known regular annual production ceased in 1906. The domestic demand for crude corundum in 1936 was satisfied by the importation of 4,790 short tons valued at \$290,221, chiefly from the Union of South Africa. Imports have increased steadily in recent years from 188 tons in 1932. The corundum is exported from the Union of South Africa principally in the form of loose crystals and fragments more than one-eighth inch in size. Only small quantities of boulder corundum are exported. Virtually all the corundum exported from the Union of South Africa in 1935 came to the United States. Most of the material is obtained from deposits on farms in northern and northeastern Transvaal, where the corundum crystals are gathered by small-farm owners from the weathered outcrops of

FIGURE 102.—Ratio of indexes of production of garnet and of silicon carbide and artificial aluminum oxide (1923-25 average=100) to the Federal Reserve Board index of industrial production (1923-25 average=100), 1920-36.

corundum-bearing veins. These deposits have been described recently by W. Kupferberger.²

Emery.—The best varieties of emery are naturally occurring, granular, intimate intermixtures of corundum and magnetite; the impure varieties contain also important quantities of hematite and spinel. Commercial deposits of emery occur in few localities in the United States, and production in recent years has been confined to a deposit of spinel-bearing emery near Peekskill, Westchester County, N. Y. The deposits in other localities have either been exhausted commercially or cannot under existing conditions meet the competition of domestic or imported Greek and Turkish emery.

Several theories have been suggested as to the origin of the Peekskill emery deposits, which are associated with the Cortlandt series of basic intrusives a short distance south and east of Peekskill. The most recent study,³ by J. W. Butler, Jr., describes these deposits in detail and concludes that the emery was formed by emanations re-

² Kupferberger, W., Corundum in the Union of South Africa: Union of South Africa, Dept. Mines, Geol. Ser., Bull. 6, Pretoria, 1935, 81 pp., 1 text fig. (map), 1 pl. (geol. map).

³ Butler, J. W., Jr., Origin of the Emery Deposits near Peekskill, N. Y.: Am. Mineral., vol. 21, no. 9, 1936, pp.537-574.

leased by the basic magma during intrusion, the magmatic emanations passing through the Manhattan-schist country rock only a short distance ahead of the magma.

The general trend in domestic production of emery has been downward since the World War and reached the lowest point in many years in 1935, when shipments were only 176 short tons. In 1936 production increased, and 325 tons were reported sold. The quantity of emery sold or used by domestic producers from 1932 to 1936 is shown in the following table.

Emery sold or used by producers in the United States, 1932-36

Year	Short tons	Value	Year	Short tons	Value
1932.....	250	\$2,781	1935.....	176	\$1,606
1933.....	1,056	12,283	1936.....	325	2,900
1934.....	189	1,800			

Sales of emery in 1936 were reported by only one company: Smith & Ellis, Peekskill, N. Y.; deposit near Peekskill, Westchester County, N. Y. The emery mine formerly operated by the Keystone Emery Mills near Peekskill, Westchester County, N. Y., was leased to Joseph de Luca, Peekskill, N. Y., in 1935 but was not operated during 1935 or 1936.

NATURAL CARBON ABRASIVES

Abrasive or industrial diamonds.—Two types of industrial diamonds are used in the United States—black diamonds (carbonados) and bort—the present demand for which is met by importations. The black diamonds, which come chiefly from the State of Bahia (Brazil) are reputed to be harder than the gem varieties of diamond and are considered especially valuable for cutting tools because they have no cleavage. The other variety of abrasive diamond (bort) is obtained chiefly from the Union of South Africa and consists of cull stones from the gem-diamond industry. Imports of abrasive diamonds in 1936 were valued at \$4,410,819, a slight increase over 1935, and included 3,779 carats of bort; 1,166,094 carats of glaziers', engravers', and miners' stones; and an unrecorded quantity of diamond dust valued at \$2,537.

Diamonds have been produced commercially at only one locality in the United States—near Murfreesboro, Pike County, Ark. About 300 carats of gem stones and bort were recovered there in 1932, but no production is known to have been made there since. In 1936, however, considerable interest is stated to have been shown in the future development of this field as a result of the general recovery in business.

ARTIFICIAL ABRASIVES

Artificial abrasives may be divided into three main groups: (1) Metallic abrasives, such as crushed steel, steel shot, and steel wool; (2) metallic carbides, chiefly silicon carbide; and (3) synthetic aluminum oxide. The table that follows gives the production of silicon carbide, aluminum oxide, and metallic abrasives. These materials compete with the natural abrasives, such as emery, corundum, and garnet. The figures represent the total output of crude material,

that is, the crude abrasive material ready for sale as such or ready for the first step in its reduction to abrasive grain. The figures for 1936, which represent the crude product alone, are not strictly comparable with those of previous years, when several manufacturers included the value of grains or additional expenditures.

Crude artificial abrasives sold, shipped, or used, from manufacturing plants in the United States and Canada, 1932-36

¹ Includes material used for refractories and other nonabrasive uses.

² Value of crude only, value of some grain included prior to 1936.

Not all the output of these materials is used for abrasive purposes. A large but undetermined part of the silicon carbide and aluminum oxide produced is used for refractory and other purposes not within the abrasive field. The total output is shown here because it is thought that the proportion used as abrasive material has not fluctuated so widely in recent years as to destroy the value of these figures for comparison with the statistics of natural abrasives.

Figure 102 shows the trends since 1920 in the combined production of silicon carbide and artificial aluminum oxide with reference to industrial production, as represented by the Federal Reserve Board index.

MISCELLANEOUS ABRASIVE MATERIALS

In addition to the materials already discussed several other commodities are used for abrasive purposes. These include a variety of oxides, silicates, and a carbonate. The oxides are all very fine grained materials and are used as final polishing agents. The oxides so used are tin oxide, or a mixture of tin oxide and oxalic acid, termed "putty powder"; rouge and crocus, forms of ferric oxide; chromium oxide; magnesium oxide or magnesia; manganese dioxide; and pure, high-grade lime. Silicates included in this miscellaneous group are river silt, clay (both natural and highly burned), and pulverized feldspar, all of which are utilized as abrasives, and clay and talc, which are used as polishing agents. Whiting (calcium carbonate) is used as a polishing agent.

FOREIGN TRADE ⁴

The total value of abrasive materials imported for consumption in the United States in 1936 was \$5,160,524, of which 85 percent was the value of industrial diamonds; the value of the imports was less than 1 percent higher than in 1935. Exports increased 5 percent in 1936, gains in abrasive wheels and other natural abrasives more than counter-balancing the decrease in the value of the exports of grindstones.

⁴ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

The following table summarizes the value of the abrasive materials imported for consumption in the United States from 1932 to 1936; the quantity and value of imports from 1934 to 1936, by kinds; and the value of domestic materials exported from the United States from 1932 to 1936.

Continued improvement in industrial activity throughout the world during 1936 was reflected in increased demand for sulphur. World production of native sulphur, supplemented by the recovery of elemental sulphur from sulphide ores and from the manufacture of fuel gases, increased substantially. Exports of crude sulphur from the United States, the principal supplier, increased 36 percent over 1935; production and exports from Japan also increased. Spain, Japan, and Norway were the principal producers of pyrites, but operations in the first country were hampered by the civil war.

Consumption of both sulphur and pyrites in the United States increased in 1936, and domestic production of pyrites rose to a new peak. In the sulphur industry the year was characterized by increased production, increased shipments, increased exports, and a steady price. Increases in severance taxes in the two principal producing States were of immediate concern to domestic producers in 1936. The following table outlines the principal features of the domestic situation in recent years.

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Salient statistics of the sulphur industry in the United States, 1925-29 (average) and 1933-36

¹ Revise. figures.

² Figures not yet available.

The total production of sulphur in the United States through 1936 has amounted to more than 38 million long tons. Virtually the entire output has been made since 1900. The principal trends in the domestic sulphur and pyrites industries during the twentieth century are shown in figures 103 and 104.

FIGURE 103.—Domestic production, domestic shipments, exports, and imports of crude sulphur, 1900-1936

FIGURE 104.—Domestic production and imports of pyrites, 1900-1936.

SULPHUR

Domestic production.—Production of sulphur in the United States in 1936 totaled 2,016,338 long tons, an increase of 24 percent over the 1,632,590 tons produced in 1935. The 1936 output was the largest

since 1931. Shipments in 1936 were 1,968,820 tons, an increase of 20 percent over 1935 and the largest since 1930. The following table records American sulphur production and shipments from 1932 to 1936.

Sulphur produced and shipped in the United States, 1932-36

Year	Produced (long tons)	Shipped		Year	Produced (long tons)	Shipped	
		Long tons	Approximate value			Long tons	Approximate value
1932.....	890, 440	1, 108, 852	\$20, 000, 000	1935.....	1, 632, 590	1, 634, 990	\$29, 300, 000
1933.....	1, 406, 063	1, 637, 368	29, 500, 000	1936.....	2, 016, 338	1, 968, 820	35, 400, 000
1934.....	1, 421, 473	1, 613, 838	28, 900, 000		.		

Eighty-five percent of the domestic output of sulphur reported for 1936 came from Texas and the bulk of the remainder from Louisiana. California and Utah produced only 4,947 long tons. Thus the two States, Texas and Louisiana, produced more than 99 percent of the domestic output.

The following table lists the sulphur mines in the United States active in 1936.

Mines that produced sulphur in the United States in 1936

Operating company	Name of mine	Location of mine
California:		
Sulphur Diggers, Inc...	Crater.....	Inyo County.
Sulphur Products Co.	Sulphur Queen.....	Do.
Louisiana:		
Freeport Sulphur Co.	Grande Ecaille.....	Plaquemines Parish.
Jefferson Lake Oil Co., Inc.....	Lake Peigneur.....	Iberia Parish.
Texas:		
Duval Texas Sulphur Co.	Boling Dome.....	Boling, Wharton County.
Freeport Sulphur Co.....	Hoskins Mound.....	Freeport, Brazoria County.
Texas Gulf Sulphur Co..	Big Hill Dome.....	Gulf, Matagorda County.
Do.....	Boling Dome.....	Newgulf, Wharton County.
Do.....	Long Point Dome.....	Long Point, Fort Bend County.
Utah: Utah Sulphur Industries.....	Utah Sulphur Industries.	Beaver, Beaver County.

Stocks.—Production exceeded shipments by a relatively small amount in 1936, resulting in a small increase in stocks. Such stocks, however, are large, amounting to 3,100,000 long tons on December 31, 1936.

Price.—The average quoted price for sulphur, as reported by trade journals, was unchanged at \$18 a ton f. o. b. mines throughout 1936. Spot prices for carlots were quoted at \$21 per ton.

Byproduct sulphuric acid.—Treatment of copper and zinc ores yields large quantities of sulphur, which are recovered at the mills as a pyrites concentrate or at the smelters as sulphuric acid. Production of pyrites concentrate is discussed in the pyrites section of this report. In smelting copper and zinc concentrates the sulphur is driven off as sulphur dioxide gas, which is used at many smelters in the manufacture of sulphuric acid. About 150,000 tons of sulphur were recovered as sulphuric acid annually from this source during the 5 years ended in 1935. Such sulphur is not included in the sulphur-production figures for the United States.

The following table gives the output of sulphuric acid as a byproduct at both copper- and zinc-smelting plants and represents virtually all

the byproduct acid produced in the United States. The acid reported is only that made from the sulphur content of the sulphide ores. The figures for 1934 and 1935 do not include the acid made from pyrites concentrate in Tennessee but do include the relatively small amount of acid made from pyrites concentrate in Wisconsin. For 1931-33 pyrites acid from both States is included. The figures for production of acid at copper plants exclude that made at Anaconda in 1933-35. Data for 1936 are not yet available.

Byproduct sulphuric acid (expressed as 60° B.) produced at copper and zinc plants in the United States, 1931-35, in short tons

	1931	1932	1933	1934	1935
Copper plants.....	436, 111	258, 994	1 301, 075	1 168, 676	1 160, 151
Zinc plants.....	426, 618	341, 340	355, 027	406, 984	443, 476
	862, 729	600, 334	1 656, 102	1 575, 660	1 603, 627

¹ Excludes acid made by Anaconda Copper Mining Co. Part of the acid made by this company in 1931 and 1932 was from pyrites concentrate and all of the acid made in 1933-35 was from this source.

² Excludes acid made from pyrites concentrate in Tennessee.

Byproduct sulphur.—A small amount of byproduct sulphur is produced annually incident to the purification of manufactured fuel gas. In 1934, 1,500 long tons of sulphur were produced from this source. Only a minor part of the output is marketed; the remainder is stored or accumulated in dumps at the various plants. Such output is not included in the sulphur-production figures for the United States.

FIGURE 105.—Comparison of index of domestic sulphur consumption with the Federal Reserve Board index of industrial activity, 1921-36.

Consumption.—The diversified application of sulphur in industry tends to preserve a consumption commensurate with the general rate of business activity, as shown in figure 105 which compares the index of domestic sulphur consumption with that of industrial production as established by the Federal Reserve Board.

The apparent domestic consumption of sulphur in 1936 was greater than in any year since 1929. Sulphur consumption from 1932 to 1936 is shown in the following table, in which it is assumed that stocks in consumers' hands are small and constant.

Apparent consumption of sulphur in the United States, 1932-36, in long tons

	1932	1933	1934	1935	1936
Shipments.....	1, 108, 852	1, 637, 368	1, 613, 838	1, 634, 990	1, 968, 820

The consumption of sulphur in various domestic industries from 1932 to 1936 has been estimated by Chemical and Metallurgical Engineering as follows:

Sulphur consumed in the United States, 1932-36, by uses, in long tons

Use	1932	1933	1934	1935	1936
Heavy chemicals.....	298, 000	491, 000	512, 000	555, 000	620, 000
Electrochemicals.....	13, 000				
Fine chemicals.....	10, 000				
Fertilizer and insecticides.....	155, 000	242, 000	247, 000	239, 000	266, 000
Pulp and paper.....	153, 000	197, 000	176, 000	204, 000	260, 000
Explosives.....	27, 000	37, 000	43, 000	42, 000	53, 000
Dyes and coal-tar products.....	34, 000	40, 000	34, 000	39, 000	46, 000
Rubber.....	18, 000	24, 000	30, 000	33, 000	39, 000
Paint and varnish.....	4, 000	4, 000	4, 000	48, 000	54, 000
Food products.....	4, 000	4, 000	4, 000	4, 000	4, 500
Miscellaneous.....	40, 000	75, 000	60, 000	68, 500	78, 000
	756, 000	1, 114, 000	1, 110, 000	1, 232, 500	1, 420, 500

Rather extensive research studies, principally by the major sulphur-producing companies, are being made on new uses for sulphur in industry and agriculture. Investigations into the use of sulphur as a fungicide and insecticide, as a fertilizer or soil conditioner, and in the control of weeds may lay the basis for expansion of its agricultural market. New and improved sulphur cements continued to attract attention during the year. Three such cements, designed particularly for making acidproof linings for tanks, acidproof floor joints, and leakproof and vibration-resisting bell joints in cast-iron and terra-cotta pipes, were reported in 1936.

Production of sulphuric acid, the chief use of sulphur in the United States, increased in 1936 over 1935, due to increases in a wide range of industrial uses. Consumption of sulphuric acid in the fertilizer industry paralleled increased demand for fertilizers as a result of a further rise in farm income. More than half the fertilizer made in the United States is phosphatic, and the bulk of the tonnage is superphosphate, virtually all of which is made by treating phosphate rock with an equal quantity of sulphuric acid. Experiments by Jacob² and associates have developed a process for producing calcined phosphate which, if applied to large-scale operation, may reduce the cost, per unit of available phosphorus, below the present cost of super-

² Jacob, K. D., Reynolds, D. S., and Marshall, H. L., Phosphate Fertilizers by Calcination Process—Volatilization of Fluorine from Phosphate Rock at High Temperatures: Amer. Inst. Min. and Met. Eng., Technol. Pub. 695, 1936, pp. 1-14.

phosphate. Typical superphosphate contains 16 to 20 percent available plant food, while calcined phosphate contains about 30 percent. Several small pilot plants now in operation use this process.

Higher concentrations of phosphate, commonly called triple superphosphate, have been made in the past but have not been well received by farmers, who never clearly understood its economic utilization.³ This product was made by treating phosphate rock with low-strength phosphoric acid, which in turn was made by treating phosphate rock with sulphuric acid.

Although phosphoric acid has been produced in this country in the blast furnace and the electric furnace it has not been used to any great extent in fertilizer manufacture. During the past several years the Tennessee Valley Authority has been making higher-strength phosphate fertilizer, utilizing phosphoric acid made in the electric furnace, and has been testing the fertilizer on growing crops under various conditions in several Southern States. During 1936 the Tennessee Valley Authority developed what appears to be a satisfactory phosphatic fertilizer, calcium metaphosphate, with about 62 percent available plant food. A method has also been developed for making the plant food in phosphate rock available by fusion of the rock under proper conditions.⁴

Consumption of sulphuric acid in petroleum refining increased in 1936 over 1935, apparently reversing the trend in the 2 previous years. The following table, which shows the consumption of sulphuric acid by industries from 1932 to 1936, is based largely on estimates by Chemical and Metallurgical Engineering. The figures on acid consumed by the fertilizer industry are supplied by the Bureau of the Census.

*Sulphuric acid (expressed as 50° B.) consumed in the United States, 1932-36, by industries, in short tons*¹

THE INDUSTRY IN 1936, BY STATES

Texas.—Texas, with an increase of 37 percent over 1935, produced 85 percent of the total output of domestic sulphur in 1936—the largest since 1931. Six operations contributed to the total, but the largest output came from the Boling Dome property of the Texas Gulf Sulphur Co. The following table, compiled from information issued by the Texas State comptroller's office, shows the quarterly production of sulphur in Texas for 1936.

Sulphur produced in Texas in 1936, by companies, in long tons

Company	First quarter	Second quarter	Third quarter	Fourth quarter	Total
Texas Gulf Sulphur Co.....	295,802	277,094	339,323	374,126	1,286,345
Freeport Sulphur Co.....	64,120	70,380	75,637	108,080	319,227
Duval Texas Sulphur Co.....	29,687	37,188	21,378	30,459	118,712
	389,609	384,672	436,338	513,665	1,724,284

Effective November 1, 1936, the tax on the production of sulphur in Texas was increased from 75 cents to \$1.03 per long ton.

The bulk of the output of the Texas Gulf Sulphur Co. came from Boling Dome in Wharton County, which has been operated continuously since first production on March 20, 1929. Production and shipments continued during 1936 from the smaller plant at Long Point, Fort Bend County. Operations at Gulf, Matagorda County, which were resumed on January 1, 1936, after the plant had been shut down for several years, were permanently discontinued in August 1936.

Although the Freeport Sulphur Co. permanently discontinued production at Bryan Mound in 1935, shipments were made from stocks during 1936, and production was continued at Hoskins Mound. The geology and operation at Hoskins Mound, which has produced more than 4,000,000 long tons of sulphur since the beginning of production on March 31, 1923, has been described by Marx.⁵

The Duval Texas Sulphur Co. continued to produce sulphur from its plant at Boling Dome in Wharton County. During the year this company was drilling for sulphur at Orchard Dome in Fort Bend County about 10 miles north of Rosenberg.

In 1936 the Jefferson Lake Oil Co. was prospecting for sulphur on certain tracts on Clemons Dome, Brazoria County, about 15 miles northwest of Freeport.

Louisiana.—Production of sulphur in Louisiana in 1936 totaled 288,099 long tons, a decrease of 23 percent from 1935. The bulk of the output came from the Grande Ecaille plant of the Freeport Sulphur Co. (279,660 tons according to the Supervisor of Public Accounts, State of Louisiana). A much smaller production (8,439 tons) was made by the Jefferson Lake Oil Co., Inc., at Jefferson Island salt dome. This property was abandoned in June 1936 and the plant dismantled after it had produced 425,902 tons.

The Louisiana State severance tax on sulphur was increased from 60 cents to \$2 per long ton effective July 28, 1936.

California.—Two operators in Inyo County reported production of sulphur in 1936. A new concern, Sulphur Diggers, Inc., acquired

⁵ Marx, Archer H., Hoskins Mound Salt Dome, Brazoria County, Tex.: Bull. Am. Assoc. Petrol. Geol. vol. 20, no. 2, February 1936, pp. 155-178.

the Crater group of claims in Inyo County in August 1936 and produced some sulphur in 1936; extensive development is planned during 1937.

Utah.—Sulphur production in Utah in 1936 came from the Utah Sulphur Industries plant at Beaver in Beaver County.

WORLD PRODUCTION

World production of sulphur in 1936, including elemental sulphur recovered in the treatment of pyrites and from gas manufacture in Germany, is estimated at 2,700,000 long tons. The following table shows the output of the principal producing countries from 1932 to 1936.

Production of sulphur in the principal producing countries, 1932-36, in long tons

[Compiled by M. T. Latus]

Country	1932	1933	1934	1935	1936
Chile.....	11,770	12,558	20,356	19,792	(1)
Italy ¹	344,450	370,676	337,966	305,498	(1)
Japan ²	83,195	112,619	133,273	162,341	172,545
Spain ³	8,113	27,128	31,130	(1)	(1)
United States.....	890,440	1,406,063	1,421,473	1,632,590	2,016,338

¹ Data not available.

² In addition, the following quantities of ground rock are reported: 1932, 25,119 tons; 1933, 24,569 tons; 1934, 21,820 tons; 1935, 13,538 tons.

³ In addition, the following quantities of sulphur rock are reported: 1932, 2,591 tons; 1933, 2,657 tons; 1934, 4,706 tons; 1935, 20,784 tons. Similar data are not available for 1936.

⁴ Refined sulphur, exclusive of that made from imported crude sulphur.

Italy.—Italy, including Sicily, is the world's second largest producer of sulphur. Production and export figures for the calendar year 1936 are not yet available, but exports for the fiscal year ended July 31, 1936, were 205,045 long tons, of which 166,809 tons were from Sicily. The minimum prices of sulphur for the fiscal year 1936-37, guaranteed by the Central Sulphur Sales Bureau (Officio Vendita di Zolfo)⁶ and established by Ministerial Decree of June 30, 1936, were:

Grade:	Lire per ton
Superior yellow.....	300
Inferior yellow.....	290
Common.....	278
Current.....	270

To furnish necessary credits to the sulphur industry, the head of the Government issued a decree late in 1936 authorizing the mining credit section of the Banca di Sicilia to increase the limit of its interest-bearing bonds from 40,000,000 to 50,000,000 lire.

Japan.—Sulphur production in Japan has been increasing during the past several years, and preliminary figures show that output in 1936 reached 172,545 long tons, the largest on record. Exports also increased to 70,853 tons in 1936 compared with 53,743 tons in 1935. The sulphuric-acid industry in Japan has been described by Matsui.⁷

Chile.—Production of sulphur in Chile is estimated at 25,400 long tons in 1936 compared with 19,792 tons in 1935. Exports, however,

⁶ For information on the Central Sulphur Sales Bureau see *Minerals Yearbook*, 1934, pp. 920-921, and subsequent issues.

⁷ Matsui, Mototaro, *The Sulphuric Acid Industry in Japan*: Jour. Soc. Chem. Ind., Japan, vol. 40, no. 2, February 1937, pp. 32B-36B.

declined from 14,822 long tons in 1935 to 10,769 tons in 1936. More than 75 percent of the 1936 exports went to other South American countries. Operations by the *Cía. Azufrera y Minera del Pacifico*, the largest producer, were resumed in January 1936, but at a reduced rate. The *Caja de Credito Minero* has established a sulphur refinery at Ollagüe on the Antofagasta & Bolivia Railway near the Bolivian frontier. The plant has a daily capacity of 100 tons of sulphur. High-grade ore containing 80 to 90 percent sulphur is sent directly to the steam autoclaves, and some of the sulphur is melted out. Low-grade ores (40 to 60 percent sulphur), together with gangue from the present autoclaves treating high-grade ore and tailings from the old sulphur refineries, are treated by flotation and the concentrates conveyed to the autoclave for refining. Recovery ranges from 40 to 80 percent.

Norway.—Data are not yet available on the output of sulphur in Norway in 1936, but the output may be estimated at 65,000 long tons. Exports in 1936 were 63,769 long tons and imports 15,509 tons. Production comes from the treatment of cupriferous pyrites at the *Thamshavn* plant of the *Orkla Metal Co.*, a subsidiary of the *Orkla Mining Co.* Capacity of this plant will be doubled by additions now being made.

The following table, compiled from official sources, shows imports and exports of sulphur in Norway from 1931 to 1936.

*Sulphur imported into and exported from Norway, 1931-36, in long tons*¹

Year	Im-ports	Exports			Year	Im-ports	Exports		
		Domes-tic	Other	Total			Domes-tic	Other	Total
1931.....	6,347	6,393	-----	6,393	1934.....	10,997	63,766	-----	63,766
1932.....	11,138	46,116	1	46,117	1935.....	14,149	65,125	-----	65,125
1933.....	7,831	58,950	-----	58,950	1936.....	15,509	63,769	-----	63,769

¹ Manedsopgaver over Vareomsetningen med Utlandet.

Germany.—Germany has no production of native sulphur, and in the past its requirements have been met by imports, largely from the United States; imports in 1936 totaled 70,272 long tons. Much of the sulphur imported into Germany is transshipped to nearby countries; exports in 1936 were 36,931 tons. In recent years production of byproduct sulphur from the manufacture of various industrial gases has been increasing, and at present more than half of the domestic requirements are met from this source.

Spain.—The output of native sulphur in Spain is augmented by production of elemental sulphur obtained in the treatment of pyrites. Figures for 1936 are not available.

Sweden.—Elemental sulphur recovered as a byproduct from smelter gases at the *Boliden* plant at *Ronskar* in North Sweden is the only sulphur produced in Sweden. Production data for 1936 are not yet available, but the plant capacity has been given as 10,000 tons per year.

Portugal.—Production of elemental sulphur from pyrites at the *San Domingos* mine in the Province of *Alemtejo*, Portugal, was begun in 1935. The output in 1936 was 9,295 long tons; imports were 405 tons.

Other countries.—Less important quantities of sulphur are produced in Argentina, Bolivia, China, Ecuador, Greece, Mexico, Netherland India, New Zealand, Southern Rhodesia, and the U. S. S. R. (Russia).

PYRITES

Domestic production.—Production of pyrites (ores and concentrates) in the United States reached a record output of 547,236 long tons in 1936. The following table gives production from 1932 to 1936, inclusive.

Pyrites (ores and concentrates) produced in the United States, 1932-36

Year	Quantity		Value	Year	Quantity		Value
	Gross weight (long tons)	Sulphur content (percent)			Gross weight (long tons)	Sulphur content (percent)	
1932.....	189,703	35.0	\$498,570	1935.....	¹ 514,192	¹ 39.5	¹ \$1,583,074
1933.....	284,311	37.9	769,942	1936.....	547,236	39.6	1,666,194
1934.....	432,524	38.8	1,216,363				

¹ Revised figures.

Of the total output in 1936, 114,598 long tons were lump and the remainder fines; the bulk of the fines were flotation concentrates. The sulphur content of the pyrites produced in 1936 was 39.6 percent (216,592 tons of sulphur) compared with 39.5 percent (203,047 tons) in 1935.

The quantity of pyrites (ores and concentrates) sold or consumed by producing companies totaled 542,976 long tons in 1936 compared with 512,802 tons in 1935. In 1936, 181,494 tons were sold by producers compared with 163,911 tons in 1935. All sales in both years were to domestic consumers. Prices quoted by trade journals are for imported pyrites and are given in cents per long-ton unit c. i. f. Atlantic ports; the average quoted was 12 to 13 cents per long-ton unit throughout the year.

Tennessee was the principal producing State in 1936; other producers were California, Colorado, Illinois, Kansas, Missouri, Montana, New York, Virginia, and Wisconsin.

THE INDUSTRY IN 1936, BY STATES

California.—The Mountain Copper Co. was the only producer of pyrites in California in 1936; output came from the Hornet mine in Shasta County.

Colorado.—Shipments of pyrites continued from the mill-tailings dump of the Colorado zinc-lead mill in Lake County during 1936. The pyrites, which averaged 35 percent sulphur, was shipped to the Denver plant of the General Chemical Co., where it is used in the manufacture of sulphuric acid.

Illinois.—Two coal operators in Illinois, one in Christian County and one in Henry County, produced and shipped 9,472 long tons of pyrites (coal brasses) recovered as a byproduct in coal-cleaning operations. The pyrites was used in the manufacture of sulphuric acid.

Kansas.—The Mineral Products Co. produced 6,902 long tons of pyrites (coal brasses) in 1936 at West Mineral in Cherokee County.

Shipments, which averaged 47 percent sulphur, were consigned to St. Louis, Mo., where they were used in making sulphuric acid. A new plant for recovering pyrites from coal-mine refuse started operation in June 1936.

Missouri.—Production of pyrites in Missouri in 1936 was 27,293 long tons and came from Crawford, Franklin, and Phelps Counties.

Montana.—The pyrites produced in Montana in 1936 came from the Anaconda Copper Mining Co. at Anaconda, where it is recovered as a flotation concentrate in the copper-plant operation.

New York.—During 1936 the St. Joseph Lead Co. produced 62,530 long tons of pyrites concentrates at its Balmat mine in St. Lawrence County. The pyrites, which ran 49.57 percent sulphur, was produced as a flotation concentrate in the treatment of ore in which zinc is the principal value.

Tennessee.—The pyrites produced in Tennessee in 1936 came from operations of the Tennessee Copper Co. and the Ducktown Chemical & Iron Co., both in the Ducktown Basin, Polk County. The product is a flotation concentrate and does not enter the market, as both companies use their entire output in the manufacture of sulphuric acid. In the latter part of 1936 the Tennessee corporation took over the properties, plants, and inventories of the Ducktown Chemical & Iron Co.

Virginia.—The only pyrites mined in Virginia in 1936 came from the Gossan mine at Cliffview, Carroll County, operated by the General Chemical Co. The ore, both lump and fine, is mined by underground methods and is used in the manufacture of sulphuric acid in the company plant at Pulaski.

Wisconsin.—The only company reporting pyrites production in Wisconsin in 1936 was the Vinegar Hill Zinc Co., in Grant County, which makes a pyrites concentrate at its magnetic separation plant at Cuba City from ore from several mines in the Platteville district.

FOREIGN TRADE

Imports of pyrites in 1936 were the largest since 1929. Spain continued to supply the bulk of our imports, but in 1936 shipments of Spanish pyrites declined owing to the civil war. The drop in imports from Spain was offset by increased shipments from Canada and by shipments from Portugal. No pyrites were exported in 1935 or 1936.

Pyrites, containing more than 25 percent sulphur, imported into the United States, 1932-36, by sources

Country	1932		1933		1934		1935		1936

Washington.....		1,524			
	253,248	374,417	366,315	397,113	429,313

If the recoverable sulphur content is calculated as 45 percent, the quantity of sulphur available in imported pyrites was approximately 195,000 long tons in 1936.

WORLD PRODUCTION

The following table shows world production of pyrites and its sulphur content. Most of the figures are taken from official sources of the countries concerned, supplemented by information from publications of the Imperial Institute and other reliable sources.

World production of pyrites (including cupreous pyrites), 1934-36, in metric tons

¹ In addition to countries listed, Belgium reports production, but figures are not shown separately.

² Data not available.

³ Includes Manchuria.

⁴ Exports.

Spain.—Spain is the principal world producer of pyrites, but war conditions undoubtedly restricted operations during 1936. Production and export figures are not available at this time.

Japan.—Preliminary figures show that the production of pyrites and cupriferous iron pyrite in Japan in 1936 was 1,692,624 metric tons. Production in recent years, which is all consumed locally, has been stimulated by increased demand for sulphuric acid.

Norway.—Production of pyrites is the principal mining industry in Norway, and output during 1936 may have reached 1 million tons. Exports were 746,080 metric tons in 1936, compared with 601,354 tons in 1935.

Portugal.—The production of pyrites in Portugal was 237,728 metric tons in 1936, compared with 214,754 tons in 1935. Exports increased from 123,961 metric tons in 1935 to 345,753 in 1936.

Canada.—Production of pyrites in Canada in 1936 totaled 115,404 metric tons containing 57,305 metric tons of sulphur, compared with 26,494 tons containing 13,174 tons of sulphur in 1935. Of the total output in 1936, 78,852 tons came from Quebec and 36,553 tons from British Columbia. In addition 11,789 short tons of auriferous pyrites concentrates were shipped to the Tacoma smelter from British Columbia for metal content and flux. Output from British Columbia came from the Britannia mill, where pyrites concentrate is produced in the treatment of ores for the extraction of copper. Quebec's production in 1936 came from the Eustis mine of the Consolidated Copper & Sulphur Co.

Canada also recovers sulphur in the form of sulphuric acid from nonferrous smelter gases. In 1936, 53,491 metric tons of sulphur were recovered as acid manufactured from smelter gases at Copper Cliff, Ontario, and at Trail, British Columbia. Elemental sulphur is also being recovered from smelter gases at Trail.

PHOSPHATE ROCK

The phosphate-rock industry in 1936 further increased mine production and shipments, reflecting the continued improvement in the fertilizer industry. Phosphate rock was mined and shipped in Florida, Tennessee, Idaho, and Montana and apatite in Virginia. Total shipments were the largest since 1930. Domestic consumption of phosphate rock continued to increase in 1936. Imports were small. Exports for the calendar year 1936 were somewhat larger than in 1935, but the trend of a 12-month moving total of monthly exports of phosphate rock turned downward late in 1936 and continued downward into 1937. Total stocks of phosphate rock in the hands of producers on December 31, 1936, were higher than those at the end of 1935. Quoted prices in the trade journals were unchanged throughout the year, although the trade reported a tendency for prices to soften.

³ Virginia included with Tennessee.

⁴ Quantity sold or used by producers plus imports minus exports.

Outstanding features of the domestic phosphate-rock industry for the past 15 years are shown graphically in figure 106. Production and exports reached their maximum in 1930, declined sharply in 1931 and 1932, and in the succeeding years recovered part of their loss. Imports reached a maximum of 45,812 long tons in 1928 and have since declined. Only 3,100 tons were imported in 1936. Stocks on hand at the end of the calendar year rose from 500,000 tons in 1925 to over a million tons in 1932 and 1934 and climbed still higher to 1,330,000 long tons in 1936 (higher than in any year since 1917). The general trend in stocks has been upward since 1925, with marked increases in 1926 and 1932.

FIGURE 106.—Salient features of the phosphate-rock industry in the United States, 1922-36.

Two general papers ¹ covering the phosphate-rock industry of the United States were published in 1936.

Domestic production and sales.—More phosphate rock was mined in the United States in 1936 than in 1935, with increases in Florida, Tennessee, and the Western States. Apatite-bearing nelsonite was mined in Virginia. State figures on mined production are given in the following table.

Phosphate rock mined in the United States, 1927-36, by States, in long tons

Distribution of sales by uses.—Phosphate rock is used chiefly in the manufacture of superphosphate, but considerable quantities are employed for other purposes. The following figures indicate the distribution of sales of phosphate rock by uses in the United States for the past 2 years.

Domestic phosphate rock sold by producers for consumption in the United States, 1935-36, by uses, in long tons

Use	1935	1936	Use	1935	1936

				2,021,031	2,192,220

¹ Revised figures.

Distribution of shipments by classes of consumers.—Figures compiled from reports by the producers show that of the total shipments of phosphate rock in the United States in 1936 (3,351,857 long tons valued at \$11,406,132) 618,795 long tons valued at \$2,046,301 were shipped to companies affiliated with the producers; 1,573,425 tons valued at \$4,749,403 were shipped to other domestic consumers; and 1,159,637 tons valued at \$4,610,428 were exported.

Prices.—Prices quoted by the Oil, Paint, and Drug Reporter for all grades of phosphate rock were unchanged throughout 1936, although the trade reported a tendency for prices to soften during the year. This tendency was probably due to the increasing stocks

of phosphate rock on hand; the declining trend in exports, shown by a 12-month moving total of monthly exports of phosphate rock; and the devaluation of certain European currencies during 1936.

*Prices of Florida and Tennessee phosphate rock, f. o. b. mine, in 1936, per long ton*¹

REVIEW BY STATES

Florida.—In Florida, the leading phosphate-rock-producing State, land-pebble and hard-rock shipments in 1936 increased in quantity and value over 1935. The quantity and value of soft-rock shipments, however, were less in 1936 than in 1935.

The following companies produced land pebble in 1936:

Amalgamated Phosphate Co., 30 Rockefeller Plaza, New York, N. Y. Plant at Brewster.

The American Agricultural Chemical Co., 50 Church Street, New York, N. Y. Plant at Pierce.

Coronet Phosphate Co., 19 Rector Street, New York, N. Y. Plant at Coronet, near Plant City.

International Agricultural Corporation, 61 Broadway, New York, N. Y. Plant at Prairie, near Mulberry.

The Phosphate Mining Co., 110 Williams Street, New York, N. Y. Plant at Nichols.

Southern Phosphate Corporation, Baltimore Trust Building, Baltimore, Md. Plant at Ridgewood.

Swift & Co., Fertilizer Works, R. F. D. 1, Bartow, Fla. Plant at Agricola.

The following companies mined hard rock in 1936:

J. Buttgenbach & Co., Lakeland, Fla.

C. & J. Camp, Ocala, Fla.

Dunnellon Phosphate Mining Co., Savannah, Ga. Mine near Hernando, Citrus County.

The following companies reported the mining of soft rock in 1936:

The Colloidal Phosphate Sales Co., Dunnellon, Fla.
 Connell & Shultz, Inverness, Fla.
 The Dixie Phosphate Co., Ocala, Fla.
 Loncala Phosphate Co., Ocala, Fla.
 M. R. Porter, Ocala, Fla.
 Soil Builders, Inc., Orlando, Fla.
 Superior Phosphate Co., Dunnellon, Fla.

¹ Includes material from waste pond operations.

² Includes small quantity of tailings.

³ Revised figures.

Cash² and Dempsey discussed accident experience in the land-pebble industry. Roundy³ and Mansfield described the geology of the hard-rock and land-pebble deposits and the methods used in prospecting public lands in these fields.

South Carolina.—Some interest was taken during 1936 in the reopening of the phosphate-rock deposits of the coastal region of South Carolina, and the General Phosphate Corporation, Beaufort, S. C., is reported to have been formed to develop phosphate deposits in the area between the Broad and Coosaw Rivers and the Atlantic Ocean.

Tennessee.—Tennessee, which ranks next to Florida as a phosphate rock-producing State, continued to recover in 1936 from the low point of 1932. Most phosphate rock marketed in 1936 came from the brown-rock fields of Maury, Sumner, Giles, Davidson, and Hickman Counties. Considerable blue rock was shipped from Lewis and Hickman Counties and a little white rock from Perry County. The

¹ Separate figures for brown rock and blue rock cannot be given without disclosing confidential data regarding blue-rock production.

The following phosphate-rock concerns were operating in Tennessee in 1936.

Armour Fertilizer Works, Room 816, Walton Building, Atlanta, Ga.
 Chaffin & Williams, Mountpleasant, Tenn.
 Charleston Mining Co., Inc., 627 East Main Street, Richmond, Va.
 J. K. Davis, Mountpleasant, Tenn.
 Federal Chemical Co., Inc., 634 Starks Building, Louisville, Ky.
 W. T. Hackney, Mountpleasant, Tenn.
 Harsh Phosphate Co., R. F. D. 7, East Station, Nashville, Tenn.
 Hoover & Mason Phosphate Co., 8 South Michigan Avenue, Chicago, Ill.
 W. T. Huff, Mountpleasant, Tenn.
 International Agricultural Corporation, Columbia, Tenn.
 Kimbro & Worley, Centerville, Tenn.
 Monsanto Chemical Co., 1700 South Second Street, St. Louis, Mo.
 Sharp & Hackney, Columbia, Tenn.
 Tennessee Valley Authority, Knoxville, Tenn.

Tennessee's share of the domestic market for phosphate rock in post-war years has ranged from 17.5 percent in 1932 to 30.0 percent in 1936. It has increased steadily from 1932 to 1936, when it exceeded any previous post-war year.

Ratio of Tennessee output to total domestic consumption of phosphate rock, 1910-14 and 1921-36

Year	Percent	Year	Percent
1910-14 (average).....	23.2	1933.....	20.0
1921-25 (average).....	18.9	1934.....	23.1
1926-30 (average).....	21.6	1935.....	28.3
1931.....	21.5	1936.....	30.0
1932.....	17.5		

Interest in Tennessee phosphate rock in 1936 was centered in the activities of the Monsanto Chemical Co. and the Tennessee Valley Authority. Early in the year the Monsanto Chemical Co. started to develop a tract of phosphate-bearing land and during the year completed the erection of a phosphate-rock sintering plant, the product of which was shipped to the electric furnaces of the company at Anniston, Ala. Late in the year this company started to erect electric furnaces near Columbia, Tenn., for the production of phosphoric acid. Mining was begun by the company in 1936 in the brown-rock field near

Columbia, Tenn.,⁴ and bottom-dump tractor trucks were used to haul the phosphate rock from the mine pit to the plant.

The Tennessee Valley Authority had several thousand acres of phosphate-bearing land under lease in central Tennessee, in Sumner, Perry, and Maury Counties, and during 1936, the rock on these lands was mined under contract and shipped to Muscle Shoals, Ala., mostly by rail but in the case of Perry County rock, by barge up the Tennessee River. Some phosphate-bearing lands were bought outright by the Tennessee Valley Authority in 1936 to insure future supplies of the rock. The Authority continued the erection of a 154-kilovolt transmission line 65 miles long from Wheeler Dam to Kraus Station, north of Columbia, where a large substation is to be erected. This line will provide current for the large load of the Monsanto Chemical Co. and service for future developments in the middle Tennessee area.

At Muscle Shoals, Ala., the Tennessee Valley Authority had two electric furnaces in service 233 days during the fiscal year ended June 30, 1936, and produced 28,690 tons of triple superphosphate and 292 tons of ferrophosphorus. A third electric furnace is being converted to utilize phosphate-rock "fines." During the fiscal year ended June 30, 1936, 31,338 tons of concentrated fertilizer which contained about 45 percent available plant food were distributed (1,986 tons the previous year), principally in the Tennessee Valley for tests and demonstrations under practical farm conditions.

In addition to the triple superphosphate the following materials were produced by the Authority during the fiscal year ended June 30, 1936 and shipped to agricultural experiment stations for testing as fertilizer: Monocalcium phosphate, 2.95 tons; dicalcium phosphate, 10 tons; calcium metaphosphate, 10.5 tons; fused phosphate rock, 14.8 tons; ground slag, 134.5 tons; and granulated slag, 3.5 tons. Laboratory research was in progress both at Muscle Shoals and the University of Tennessee at Knoxville on problems related to the development and production of new concentrated plant foods, especially phosphates.

The preparation of phosphoric acid, triple superphosphates, and other products at the T. V. A. plant at Wilson Dam, Ala., is described in detail in three reports.⁵

Virginia.—The Southern Mineral Products Corporation (subsidiary of the Vanadium Corporation of America) continued to develop the nelsonite deposit at Piney River and produced apatite and ilmenite. During the year this company sold its chemical unit to the Virginia Chemical Co., but retained its nelsonite ore deposits and milling and concentrating plant at Piney River.

Western States.—In 1936, as in 1935, only two phosphate-rock-producing companies were operating in the Western States, one in Idaho and one in Montana. The quantity and value of the phosphate rock marketed in each State were greater than in 1935.

Idaho was the larger producing State. Most of the rock produced came from the Conda No. 1 mine of the Anaconda Copper Mining Co., Conda, Caribou County, Idaho, but a considerable quantity came

from the Conda No. 3 mine. According to the company's annual report,⁶ 22,589 tons of treble superphosphate and phosphoric acid were produced at Anaconda, Mont., in 1936. A small quantity of the phosphate rock from this property was sold for direct application to the soil, and a little was exported.

In Montana the Montana Phosphate Products Co., Trail, British Columbia, operated the Anderson mine near Garrison, Powell County, under contract with William Anderson and shipped the phosphate rock mined to Canada. According to the annual report of the Consolidated Mining & Smelting Co. of Canada, Ltd.,⁷ 40,345 short tons (36,022 long tons) of phosphate rock were produced at this property in 1936 and 165 feet of drifts and 598 feet of raises driven during the year.

A detailed description of the phosphate-rock deposits near Maxville, Philipsburg, and Avon, Mont., by J. T. Pardee, of the United States Geological Survey, was published during 1936.⁸ This report covers the geology, composition, reserves, development, treatment, production, and markets of the phosphate rock in several of the productive phosphate-rock areas of the State.

Western States phosphate rock sold or used by producers, 1932-36

FOREIGN TRADE⁹

Imports.—In recent years relatively little phosphate rock has been imported into the United States. In 1928 imports of phosphate rock reached a post-war maximum of 45,812 long tons, but they have since declined, and in 1934 no phosphate rock was imported into this country. Imports in 1935 and 1936 were confined almost solely to shipments from the U. S. S. R. (Russia), amounting to 3,699 and 3,100 long tons, respectively. The following table shows imports of phosphate rock from 1932 to 1936 by countries:

⁶ Anaconda Copper Mining Co., Report for the Year Ended December 31, 1936.

⁷ Consolidated Mining & Smelting Co. of Canada, Ltd., Thirty-first annual report, for the 12 months ended Dec. 31, 1936.

⁸ Pardee, J. T., Phosphate Rock Near Maxville, Philipsburg, and Avon, Mont.: U. S. Geol. Survey Bull. 847, 1936, pp. 175-188.

⁹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

¹ None reported in 1934.

² Less than 1 ton.

³ Apatite.

⁴ Includes 3,599 long tons valued at \$28,829 known to be apatite.

Phosphatic fertilizers other than phosphate rock imported for consumption in the United States include various bone products, guano, and basic slag. In 1936 the quantity and value of imports of basic slag were slightly less than in 1935, while the quantity and value of imports of the other groups increased. Imports for 1932-36 are given in the following table:

Phosphatic fertilizers (other than crude phosphate rock) imported for consumption in the United States, 1932-36

1934.....	993,493	5,008,532			

Exports of land-pebble and other phosphate rock in 1936 increased in quantity and value over 1935. Shipments to Belgium increased sharply, and those to Canada, Germany, Japan, Sweden, and the United Kingdom also were higher, while exports to Spain dropped.

Exports of high-grade hard rock likewise increased in quantity and value, principally because of increased takings by Germany. The following table shows the total exports of high-grade hard rock, land-pegble, and other phosphate rock, also shipments of each type of rock to various foreign countries annually from 1932 to 1936.

Phosphate rock, ground or unground, not acidulated, exported from the United States, 1932-36, by countries

Exports of high-grade, hard-rock phosphate from the different customs districts are shown in the following table. In 1936 most of this type of rock was exported from the Florida district, but a large quantity of high-grade, hard-rock phosphate was shipped from the Montana-Idaho district to Canada.

High-grade hard-rock phosphate exported from the United States, 1935-36, by customs districts

¹ Less than 1 ton.**WORLD PRODUCTION**

Data available at present indicate that the United States was the leading producer of phosphate rock in 1936, with Tunisia second and Morocco third. Production in the United States increased in 1936 over 1935, while that in Tunisia, Algeria, and Morocco declined slightly. The U. S. S. R. (Russia) is an important producer of phosphate rock, due largely to the development of its Kola Peninsula apatite deposits, although in 1935 it is reported to have produced 1,750,300 tons of low-grade phosphate rock.

Statistical details of world production, trade, and consumption of phosphate rock for 1932, 1933, and 1934 were published during 1936.¹⁰

¹ Exports during fiscal year ended Mar. 31 of year following that stated.² Data not available.³ Estimated (Imp. Inst., London).⁴ Exports.⁵ Shipments, including exports as follows: 1932, 972,692 tons; 1933, 1,091,174 tons; 1934, 1,255,847 tons; 1935, 1,296,052 tons; 1936, 1,247,923 tons.⁶ Exports during fiscal year ended June 30 of year stated.⁷ Apatite concentrates. Production of apatite ore in 1935 amounted to 1,555,300 tons; in addition 1,750,300 tons of low-grade phosphate rock were reported.¹⁰ Gray, A. N., Statistics of Phosphate and Superphosphate for 1934. I, Phosphate Rock: Superphosphate (London), vol. 9, no. 1, 1936, pp. 1-7.

IMPROVEMENTS IN TECHNOLOGY

The calcination of phosphate rock for the removal of the fluorine content and the conversion of the insoluble phosphate rock into citrate-soluble form readily available as plant food were described in two papers.¹¹

An apparatus for the determination of fluorine in phosphate rock by the Willard and Winter method was described by Reynolds and associates.¹²

SUPERPHOSPHATES

Salient features of the superphosphate industry in the United States are shown in the following table covering the 4-year period, 1933-36, inclusive.

Summary of statistics for superphosphate industry in the United States, 1933-36

	1933	1934	1935	1936

¹ Less than 1 ton.

Since January 1, 1935, monthly imports of superphosphate have been subdivided into three classes: (1) Superphosphates standard (not over 20 percent P_2O_5 content), (2) superphosphates treble (over 20 percent P_2O_5 content), and (3) superphosphates ammoniated.

Statistics for 1934, covering international trade in superphosphate and production and consumption of superphosphate in various countries, were published early in 1936.¹⁴

BASIC SLAG

Basic slag, a byproduct of the manufacture of basic steel, contains considerable phosphorus in a form readily available as plant food, and it has been used as phosphorus-bearing fertilizer since the early eighties, following the invention of the Thomas and Gilchrist modification of the Bessemer process of steel making in 1878. In Germany, Belgium, England, Luxemburg, and France, where highly phosphatic iron ores are used in the manufacture of steel and where large quantities of basic slag are available, it has developed into an important source of phosphorus, competing directly with phosphate rock and superphosphates. The production of basic slag in recent years is shown in the following table. European consumption of basic

slag (known as Thomas slag) in 1928 exceeded 4 million tons, about 58 percent of which was used in Germany.

¹ Bureau of Foreign and Domestic Commerce, World Trade Notes: Vol. 10, no. 36, 1936, p. 4.

Although the production and consumption of basic slag is confined principally to European countries, some is produced in the United States, principally from the Birmingham district of Alabama,¹⁵ where about 35,000 tons are produced annually by the Tennessee Coal, Iron & Railroad Co., a subsidiary of the United States Steel Corporation. Here it is a byproduct of the basic open-hearth process of making steel from the red-hematite iron ores of the Birmingham district. The slag formed in the furnaces in this operation is poured off, cooled, crushed, and ground to a fine powder (90 percent of which will pass through a 100-mesh screen) which is sold as a soil conditioner with a guaranteed minimum of 8 percent phosphoric acid.

A small quantity of basic slag (from 131 to 3,998 long tons annually) has been imported into the United States in recent years.

In general, conditions in the talc and ground-soapstone industry during 1936 were better than in any year since 1929. Ground soapstone is included with talc in this chapter because soapstone is essentially an impure talc and when pulverized is used for the same purposes and competes directly with ground talc. North Carolina pyrophyllite also is included, following the precedent established many years ago by the United States Geological Survey in its annual reviews of the talc industry. Although pyrophyllite resembles talc in certain physical properties and uses, it is an aluminum silicate resembling clay in chemical composition and is classed by several mineralogists as a subvariety of kaolinite.

Sales.—Sales of 216,191 short tons of talc and soapstone valued at \$2,343,171 exceeded corresponding figures for 1935 by 25 and 27 percent, respectively. The increases resulted principally from a greater output of ground material which represented about 95 percent of the total production. A slightly higher tonnage of crude material was offset by a decline in the quantity of sawed and manufactured products, although the value of the latter increased nearly 50 percent.

Talc and ground soapstone sold by producers in the United States, 1932-36, by classes

¹ Includes talc only.

Production by States.—The output of talc and ground soapstone in 1936 was obtained from 35 mines in 9 States, compared with 33 mines in 11 States in 1935. Talc was produced in California, Georgia, Maryland, New York, North Carolina, Vermont, and Washington; soapstone in California, Pennsylvania, Virginia, and Washington; and pyrophyllite in North Carolina.

¹ Soapstone sold in slabs or blocks is included under "Dimension stone" in the chapter on Stone.

MARKETS

The trend in sales of talc and soapstone has always followed rather closely the general business cycle; the principal exception in the last few years was the unusual rise in 1933 followed by a rather sharp decline in 1934. (See fig. 107.) However, the welfare of the talc and soapstone industry depends more specifically on the demands of the paint, paper, roofing, and rubber industries, and changes in consumption within that group are of particular significance to the producers. Declines in consumption of talc in some industries have been compensated by greater use of talc in others, so that total production reached a relatively high level in 1936. Data available for 1931 and 1936 showing percentages of the output purchased by various industries indicate the changes that have taken place within that 5-year period. The most evident decline was in sales to paint manufacturers—from 48 percent of the total in 1931 to 29 percent in 1936. This situation occurred despite appreciable increases in sales of paint since 1932 and suggests the possibility of a permanent loss in that market. The decline from that source, however, was overcome partly by greater sales to manufacturers of rubber products and roofing and to a considerable extent by the use of talc in ceramics. The increased demand from the rubber industry indicates not only a greater consumption of rubber products but also a displacement of

mica, with which talc competes for use in dusting molds. The advance in sales to the ceramic industry is particularly important because it has been due mainly to the greater use of talc as a constituent of wall tile, the production of which has been increasing with the sharp rise in building construction.

*Percentages of ground talc and soapstone sold to consuming industries in the United States, 1931 and 1936*¹

Industry	1931	1936	Industry	1931	1936
Paint.....	48	29	Toilet preparations.....	3	1
Paper.....	16	17	Foundry facings.....	1	1
Roofing.....	11	13	Other.....	9	14
Rubber.....	11	15			
Ceramics.....	1	10		100	100

¹ Includes 96 percent of sales in 1931 and 90 percent in 1936.

Demands for talc for paper manufacture appear to have remained rather constant; 16 percent of the total output of the ground product in 1931 and 17 percent in 1936 were sold to this industry. A comparison of the production of talc with that of fine paper shows a remarkable similarity in trends during the last 5 years, especially in 1933 and 1934, when there was an unusual rise and decline in both industries. It is

FIGURE 107.—Trends in production of talc and ground soapstone, sales of fine paper, consumption of rubber, and industrial production, 1927-36. Indexes for paper and rubber computed from data of Bureau of Foreign and Domestic Commerce; industrial production index is from the Federal Reserve Board.

difficult to explain the relationship in view of the rather small percentage of talc sold to the paper industry, nevertheless the similarity suggests a means of estimating the annual talc production in advance of official statistics. Data for fine-paper production appear monthly in the Survey of Current Business, published by the United States Department of Commerce.

Sales of high-grade talc for the manufacture of toilet preparations were smaller than usual in 1936, comprising only 1 percent of the total production. The demand from manufacturers of foundry facing remained about the same as in the past few years.

Other markets for ground talc and soapstone in 1936 included many industries, none of which purchased a large quantity but which in the

aggregate consumed 14 percent of the entire output. Some of the miscellaneous uses reported by producers were as a cloth filler; for cotton bleaching; as a polish for rice, peanuts, and glass; and as an ingredient of lubricants, concrete, plaster, and insecticides.

PRICES

The price of talc and ground soapstone in 1936, as represented by the average value per ton of all grades of material, was \$10.84—14 cents a ton more than in 1935 and the highest since 1932. The slight increase was due principally to the higher value of sawed and manufactured material, which was \$146.51 per ton in 1936 and \$75.16 in 1935. The average value per ton of ground talc and soapstone was virtually the same in both years, and the value of crude increased only 12 cents a ton.

Average values per ton of talc and ground soapstone in each year from 1927 to 1936, inclusive, are shown in the following table.

Average value per ton of talc and ground soapstone sold by producers, 1927-36

DEVELOPMENTS IN THE INDUSTRY

A cooperative investigation by the Bureau of Mines, the Missouri School of Mines and Metallurgy, and the Eastern Magnesite Talc Co. determined that talc concentrates and magnesite tailings could be obtained through beneficiation of Vermont talc-magnesite ores by flotation.

Up to now technical developments in the talc industry have been confined largely to improvements in the mechanical preparation of various products. Little or no attempt has been made to beneficiate talc rock by recognized ore-dressing methods. Selective mining when necessary, followed by crushing and grinding dry to 200-mesh or finer by pebble mills or other crushing devices in closed circuit with air separators, has been the customary method of preparation. In certain instances a moderate degree of beneficiation has been obtained by rejecting the separator tailings. Although the talc recovery was low the procedure was justified because it enabled the operator to meet the demands of the trade for specific grades. The disposal of the separator tailings containing 30 to 40 percent of talc became increasingly serious as the demand for the higher grades increased. In some instances as much as 3 tons of talc rock were required to produce 1 ton of the desired grade. The 2 tons accruing as a low-grade product had relatively little value and were difficult to market.

Flotation promises a means for eliminating undesirable impurities from the rejected material and low-grade talcs and at the same time may yield a product with better texture and "feel" from higher-grade talcs.

The United Feldspar Corporation, through its subsidiary, the Tennessee Mineral Products Corporation, acquired the entire capital

stock of the Carolina Pyrophyllite Co., Staley, N. C. Plans have been made to erect a mill at or near the mines to grind the raw material.²

The talc-schist property, formerly operated by Herbert I. Oursler, Mariottsville, Md., is now operated by the Seaboard Operating Co., 430 Hearst Tower Building, Baltimore, Md., a subsidiary of the Clinchfield Sand & Feldspar Corporation. The old mill has been reconditioned.

FOREIGN TRADE

Imports.—Imports of talc and soapstone, classified as talc, steatite, or soapstone and French chalk, crude, manufactured, or ground, amounted to 24,519 short tons valued at \$456,667 in 1936. Compared with imports in 1935 the quantity was 3 percent greater and the value 7 percent less. The increase in quantity resulted from the larger amounts furnished by China, Canada, and Norway and the decline in value from the smaller amounts of high-priced materials purchased from Italy and France. Canada continued to be the largest source of supply, and Italy and France were next in importance.

Talc imported for consumption in the United States, 1932-36

Exports.—Exports of talc and soapstone continued to increase in 1936. Crude talc has been classified separately since 1932, and the 1936 exports of 6,669 short tons valued at \$115,434 exceeded those of the preceding 3 years. The total value of talc exports, including talcum, face, and compact powders, was \$803,571, which was higher than in any year since 1931.

WORLD PRODUCTION

Talc occurs rather widely throughout the world, and available information indicates that the mineral is produced in at least 24 countries. Data for 1936 are limited, but undoubtedly the United States continued to lead all other countries in quantity produced. The next largest producing countries, in the order of their importance, are usually France, China (including Manchuria), and Italy.

FLUORSPAR

Increased demand for fluorspar, chiefly by manufacturers of basic open-hearth steel and hydrofluoric acid, the two largest consumers, was reflected by the consumption of 182,400 short tons of fluorspar in 1936 compared with 137,400 tons (revised figure) in 1935. This improved demand resulted in the reopening of many inactive mines, the development of several new mines and prospects, and the resumption of operations by the Aluminum Ore Co. at the flotation mill at Rosiclare, Ill., and the concentrating mill at Marion, Ky. In consequence, mine production and shipments of fluorspar in 1936, as well as imports, were substantially higher than in 1935. In fact, so great was the demand for fluorspar in 1936 that shipments from domestic mines have been exceeded in only 3 years—1917, 1918, and 1920.

Total sales of fluorspar to consumers in the United States in 1936 were 201,148 short tons (176,231 tons from domestic mines and 24,917 tons imported) compared with 140,047 tons (revised figure) in 1935 (123,741 tons (revised figure) from domestic mines and 16,306 tons imported). Total sales to the steel industry increased from 106,870 tons (revised figure) in 1935 to 156,714 in 1936, whereas sales to manufacturers of hydrofluoric acid advanced from 11,048 tons in 1935 to 21,510 in 1936. In fact, sales of acid-grade fluorspar in 1936 were the largest ever recorded, and shipments from domestic mines have been exceeded in only 2 years, 1928 and 1929. Although nonferrous smelters usually provide a comparatively small market for fluorspar, the gain in shipments from 868 tons in 1935 to 1,931 tons in 1936 was noteworthy. Sales to the enamel trade also increased, but those to the glass industry were slightly less than in 1935.

¹ Revised figures.² Figures not available.

The improved demand for fluorspar in 1936 was accompanied by a substantial increase in the average selling price of fluxing-gravel fluorspar, from \$13.76 a ton f. o. b. Illinois-Kentucky mines in 1935 to \$16.53 a ton in 1936. The average selling price of all grades increased from \$15.04 a short ton in 1935 to \$17.65 in 1936. The average selling price of imported fluxing-gravel fluorspar increased from \$18 a short ton in 1935 to \$19.04 in 1936.

Other important developments in 1936 were increases of 42 and 193 percent in the consumption of acid-grade fluorspar as a refrigerating medium and in the manufacture of aluminum, respectively; record shipments (46,895 tons) by barge for delivery at upper Ohio River landings; resumption of imports from France; shipments of 4,180 tons from Newfoundland to the United States; reduction in producers' stocks of gravel fluorspar; and increased shipments from the Chaffee County (Colo.) field, of which a considerable part moved to eastern markets.

Available data on trends in production, imports, consumption, and average value of fluorspar over a series of years are shown in figure 108.

Production and shipments.—Fluorspar was known to have been produced in 1936 at 100 mines and prospects, and small quantities were recovered at an undetermined number of other prospects and reclaimed from mill ponds, waste dumps, and old workings of abandoned mines. All operations yielded about 168,000 short tons of merchantable fluorspar compared with about 102,000 tons in 1935. In spite of

FIGURE 108.—Trends in production and average value per ton of fluorspar in the United States, 1880-1936; in imports, 1910-36; and in consumption, 1926-36.

the large number of properties worked in 1936, however, 27 mines produced 87 percent of the total output.

Shipments of fluorspar from domestic mines in 1936 aggregated 176,231 short tons valued at \$3,111,268, increases of 42 percent in quantity and 67 percent in total value over 1935. Shipments in 1936 were equivalent to 141 percent of the average annual tonnage shipped in the 5-year period 1926-30. Of the 1936 shipments, 46,895 tons were shipped by barge for delivery at upper Ohio River landings compared with 23,800 tons in 1935.

The average value of all grades was \$17.65 a ton in 1936, or \$2.61 more than the 1935 average. The value recorded for domestic fluorspar is the price paid f. o. b. mine shipping point by the consumer and excludes cost of containers. The average value per ton of the fluorspar shipped to steel plants from the Illinois-Kentucky district was \$16.53 in 1936 compared with \$13.76 in 1935 and from the Chaffee County (Colo.) field \$8.16 in 1936.

The following table presents such details of shipments of fluorspar by States from 1934 to 1936 as may be published without revealing, except by permission, operations of individual producers.

Miscellaneous.....	1,000	300	1,800	900
	¹ 137,400	58,000	182,400	72,600

¹ Revised figures.

The following table shows the relation of consumption of fluorspar to production of basic open-hearth steel, 1932-36, and stocks of fluorspar at such steel plants at the close of each year.

Consumption and stocks of fluorspar at basic open-hearth steel plants, 1932-36

	1932	1933	1934	1935	1936
Production of basic open-hearth steel ingots and castings.....long tons.	11,742,682	20,057,146	23,440,000	30,447,000	43,615,000
Consumption of fluorspar in basic open-hearth steel production.....short tons.	36,300	61,300	81,000	99,600	133,900
Consumption of fluorspar per ton of steel made.....pounds.	6.2	6.1	6.9	6.5	6.1
Stocks of fluorspar on hand at steel plants at end of year.....short tons.	55,000	56,000	45,500	47,500	59,200

The quantity of fluorspar used by individual plants per ton of basic open-hearth steel produced ranges from 1 to 50 pounds—a relatively small proportion of the furnace charge. The average is generally 5 to 8 pounds; it decreased from 6.5 pounds in 1935 to 6.1 in 1936. The following table shows the variation in average consumption of fluorspar per ton of basic open-hearth steel over a 5-year period in certain plants that make about 88 percent of the total.

Average consumption of fluorspar per ton of steel, 1932-36, in pounds

1932	1933	1934	1935	1936	1932	1933	1934	1935	1936
14.176	18.944	14.443	13.243	13.187	5.302	5.659	7.488	7.048	6.734
4.572	3.864	4.766	4.182	4.792	6.646	6.754	6.584	9.347	10.495

¹ Iron Age, vols. 137 and 138, 1936.

Stocks at mines or shipping points.—According to reports of producers the total quantity of fluorspar in stock at mines or shipping points at the close of 1936 was 53,981 short tons, a decrease of 16 percent from 1935. These stocks comprised about 24,000 tons of crude fluorspar (calculated to be equivalent to 12,700 tons of ready-to-ship fluorspar) and 29,958 tons of ready-to-ship fluorspar.

¹ The greater part of this crude (run-of-mine) fluorspar must be beneficiated before it can be marketed.

² Revised figures.

INDUSTRY IN 1936, BY STATES

Arizona.—A carload of fluorspar was produced at the Luckie property near Duncan, Greenlee County, Ariz., in 1936. It was mined to obtain samples in order to test the grade and suitability of the material for certain purposes. The material was shipped to a steel plant.

Colorado.—Shipments of fluorspar from Colorado in 1936 were 9,412 short tons compared with 6,978 tons in 1935. Of the 1936 shipments 8,072 tons went to steel plants, 510 tons to iron foundries, and the rest to ferro-alloy and cement plants and nonferrous-metal refineries. Shipments in 1936 comprised 40 tons from Boulder County, 5,101 tons from Chaffee County, 15 tons from Jackson County, and 4,256 tons from Mineral County. Shipments from Colorado in 1936 were the largest since 1926, and those from Chaffee County were the largest since the field was opened. The movement of 26 carloads of fluorspar from Chaffee County to eastern markets indicates low production costs. Virtually all other fluorspar shipped from Chaffee County went to midwest consumers.

Illinois.—Increased demand for fluorspar in 1936 stimulated activity in Illinois and resulted in much prospecting and development work and in the mining, milling, and shipment of substantially greater quantities of fluorspar in 1936 than in 1935. In fact, shipments in 1936 were the largest since 1922. Several mines either inactive or virtually so in 1935 were reopened; the flotation plant of the Aluminum Ore Co., inactive since 1931, resumed operations; and a milling plant was under construction at the Cave in Rock mine.

Approximately 136,000 short tons of fluorspar-bearing material, equivalent to about 76,000 tons of merchantable fluorspar, were mined at 25 mines or prospects in Illinois in 1936 compared with about 87,000 tons, equivalent to about 40,000 tons of merchantable fluorspar, mined

at 18 mines or prospects in 1935. Of the merchantable fluorspar produced in 1936, 43,000 tons were from mines where the fluorspar occurs in veins, chiefly in fault fissures, and 33,000 tons from mines where the fluorspar occurs in flat-lying tabular masses, locally called blanket formations.

Fluorspar-bearing material milled in Illinois in 1936 totaled about 136,000 tons, from which 73,000 tons of merchantable fluorspar were recovered—a ratio of 1.863 : 1.

Shipments from Illinois were 82,056 tons in 1936 compared with 44,120 tons in 1935. Of the total, 32,344 tons were shipped by barge for delivery at upper Ohio River landings compared with 12,312 tons in 1935.

The chief producing mines in 1936 were the Stewart, Hamp, Crystal, Hillside, Lee, Daisy, Spar Mountain, Victory, and Douglas; these supplied about 89 percent of the total merchantable fluorspar produced. The remainder of the output came from the Lead Hill, Argo, Blue Diggings, Good Hope, Diamond, Rose, Humm, Preen, Cave in Rock, Eureka Nos. 1 and 5, Boundary Shaft, and Dimick mines and various small prospects.

The flotation plant at Rosiclare treated 9,058 short tons of ore and tailings in 1936, from which a considerable quantity of No. 1 concentrates suitable for use in the manufacture of hydrofluoric acid was recovered. The mill feed in 1936 included 1,203 tons of fluorspar-bearing material of Kentucky origin, and the concentrates recovered therefrom have been credited to Kentucky in the statistics.

Kentucky.—In Kentucky, as in Illinois, improved demand for fluorspar in 1936 resulted in renewed activity at several mines, reopening of the milling plant of the Aluminum Ore Co., improvements and additions to mill equipment, and considerable prospecting and development work. In fact, so great was the demand for Kentucky fluorspar that shipments (80,241 short tons) have been exceeded in only 1 year, 1918. Consequently, almost any source that would yield fluorspar was drawn upon. Although most of the output came from mines of the fissure-vein type, which use mechanical equipment and follow more or less orderly systems of mining, a considerable tonnage was reclaimed from mill ponds, waste dumps, old workings of abandoned mines, and numerous small prospects.

Production of merchantable fluorspar in Kentucky in 1936 was about 78,000 short tons compared with 51,300 tons in 1935, and shipments were 80,241 tons compared with 68,679 tons in 1935.

Fluorspar was mined at five properties in Caldwell County in 1936, but most of the output came from the Hollowell & Hobby mine. Production of merchantable fluorspar in the county was about 3,800 short tons compared with 2,400 tons in 1935.

Reopening of the Lafayette, Keystone, and Pigmy mines and increased output, chiefly at the Watson (Eagle) and Davenport mines, are evidenced by the production of about 38,500 tons of merchantable fluorspar in Crittenden County in 1936 compared with 19,400 tons in 1935. Although fluorspar was produced at a large number of small mines and prospects and reclaimed from an undetermined number of mill ponds, waste dumps, and old workings of abandoned mines, about three-fourths of the production in the county came from eight mines—the Memphis, Watson (Eagle), Lafayette, Keystone, Pigmy, Davenport, Blue & Marble, and Bachelor.

About 35,000 short tons of merchantable fluorspar were produced in Livingston County in 1936 compared with 29,500 tons in 1935. The chief producing mine was the Klondike, with an output of about 27,000 tons. The Nancy Hanks, John-Jim, C. R. Babb, and Bonanza mines were also important producers; the remainder of the output was from various small mines and prospects and from mill tailings.

The Faircloth mine near Wilmore, Woodford County, which had long been inactive, was reopened in 1936, and 650 tons of fluorspar (600 tons of fluxing gravel, 30 tons of foundry lump, and 20 tons of acid lump) were produced and shipped.

Nevada.—Shipments of fluorspar from Nevada were 2,126 short tons in 1936 compared with 1,040 tons in 1935 and were the largest ever recorded. Of the 1936 shipments, 2,084 tons went to steel plants, 34 tons to cement plants, and 8 tons (ground) to enamel manufacturers.

The chief producing mine in Nevada in 1936 was the Baxter in Mineral County, with record shipments of 1,890 tons. The other active mine was the Daisy in Nye County, which shipped 236 tons.

New Hampshire.—The fluorspar mine near Westmoreland, Cheshire County, shipped 257 short tons of fluorspar in 1936 compared with 12 tons in 1935. Shipments in 1936 comprised 226 tons to steel plants, 1 ton to foundries, and 30 tons of acid grade for use in the manufacture of hydrofluoric acid. The shaft at this mine was deepened and a second level started in 1936.

New Mexico.—Shipments of fluorspar from New Mexico were 2,045 short tons in 1936 compared with 2,726 tons in 1935 and comprised 1,748 tons of ground fluorspar and 297 tons of metallurgical run-of-mine fluorspar.

Production of fluorspar in New Mexico in 1936 came from deposits near Deming in Luna County and from a newly opened deposit near Silver City in Grant County.

Utah.—Shipments of fluorspar from Utah in 1936 were 54 tons of metallurgical gravel compared with 180 tons in 1935. The deposit, opened in 1935, is in Beaver County, and the ore is hauled 25 miles to Lund for shipment. The fluorspar is reported to be high-grade and the vein of considerable width.

TRENDS IN EMPLOYMENT AND OUTPUT PER MAN-HOUR

The following table gives details on employment at fluorspar mines and mills, the quantity of ore mined and milled, and the average output of fluorspar per man-hour for 1933-35 by years, States, and groups of States. Corresponding statistics by States and groups of States for the 6-year period 1926-31 and supplementary data are given in the chapter on Fluorspar and Cryolite in Minerals Yearbook, 1935. Although information on employment at all operations was not reported, the compilations include mines producing about 90 percent of the total output for the 3-year period 1933-35; therefore the figures are regarded as representative. The reports received from the producing companies do not include salaried officials and office workers or an undetermined number of employees engaged in hauling fluorspar, as such work usually is done on a contract basis, and no record of it is kept by the mining companies.

Employment at fluorspar mines and mills in the United States, quantity of ore mined and milled, and average output of fluorspar per man 1933-35, by States¹

¹ Includes men and employment at mines and mills producing from 83 percent in 1933 to 97 percent in 1935 and averaging 90 percent of the total fluorspar produced during the 3-year period covered by study; excludes officials, clerks, and other subordinated salaried employees as well as all men engaged in contract hauling of fluorspar.

² Includes a comparatively small quantity of run-of-mine fluorspar not washed or milled.

IMPORTS AND EXPORTS¹

The total imports of fluorspar for consumption in the United States were 25,504 short tons (10,028 tons containing more than 97 percent and 15,476 tons containing not more than 97 percent calcium fluoride) valued² at \$259,262 in 1936, compared with 16,340 tons (10,578 tons containing more than 97 percent and 5,762 tons containing not more than 97 percent calcium fluoride) valued² at \$170,049 in 1935. The value assigned to the foreign fluorspar in 1936 averaged \$10.17 a ton. The cost to consumers in the United States also includes duty, loading charges at the docks, ocean freight, insurance, consular fee, and freight from docks to consuming points. The duty on fluorspar containing more than 97 percent calcium fluoride is \$5 per short ton and on fluorspar containing not more than 97 percent calcium fluoride, \$7.50.

Of the imports in 1936 about 61 percent was metallurgical-gravel fluorspar, 5 percent ceramic-ground fluorspar, and 34 percent acid (chiefly lump) fluorspar. The metallurgical-gravel fluorspar was imported from France, Germany, Newfoundland, and Spain; the ceramic-ground fluorspar from Germany and Spain; and the acid-grade fluorspar from Germany, Newfoundland, Spain, and Union of South Africa. Imports were equivalent to 14 percent of the total shipments of domestic fluorspar in 1936 compared with 13 percent in 1935.

The following table, compiled from data courteously furnished the Bureau of Mines by importers, shows the quantities of imported fluorspar delivered to consumers in the United States in 1935 and 1936 and the selling price at tidewater (duty paid), irrespective of the year

¹ Figures on imports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce; those on exports supplied by the producers. No exports of fluorspar recorded by the Bureau of Foreign and Domestic Commerce.

² As defined in sec. 402 of the tariff act of 1930, "The value of imported merchandise . . . is the foreign value or the export value, whichever is higher—that is, the market value or the price at which the merchandise, at the time of exportation to the United States, is offered for sale in the principal markets of the country from which exported, including the cost of containers or coverings and all expenses (including any export tax) incident to placing the merchandise in condition ready for shipment to the United States."

of importation into the United States; it differs from the preceding table, which shows the quantities received in the United States during 1935 and 1936. The quantities in this table are based on the actual outturn weight ascertained by sworn weighers and represent the weight on which duty was paid and entries were liquidated.

Imported fluorspar delivered to consumers in the United States, 1935-36

Manufacturers of glass and enamel purchased a much smaller proportion of their fluorspar supply from importers in 1936 than in 1935. For example, in 1936 such manufacturers purchased 938 short tons from importers and 16,263 from domestic producers, whereas in 1935 they purchased 2,889 and 14,343 tons, respectively. In 1935 most of the acid-grade fluorspar was supplied by importers, but in 1936 the greater part came from domestic mines. Specifically, in 1936 domestic producers supplied 12,627 and importers 8,883 tons, whereas in 1935 domestic producers supplied 3,333 and importers 7,715 tons.

Producers of fluorspar reported exports of 240 short tons valued at \$4,079 in 1936 compared with 313 valued at \$4,651 in 1935. In both years all the fluorspar exported went to Canada.

Fluorspar reported by producers as exported from the United States, 1932-36

FLUORSPAR IN FOREIGN COUNTRIES

*Canada.*³—The production of fluorspar in Canada was 75 short tons valued at \$900 in 1936 compared with 225 tons valued at \$2,700 in 1935. The output in both years was from Ontario.

Imports of fluorspar into Canada were 11,194 tons valued at \$95,268 in 1936 compared with 11,591 valued at \$92,775 in 1935.

France.—France was an annual exporter of fluorspar to the United States from 1924 to 1933, and in 1930 exports reached 23,313 short tons. Since 1933, however, chiefly owing to the unfavorable rate of

³ Dominion Bureau of Statistics, Preliminary Report on the Mineral Production of Canada During the Calendar Year 1936; Ottawa, 1937, p. 26.

exchange, France has been unable to export fluorspar to this country at a profit. The more favorable rate of exchange since September 28, 1936, prompted resumption of exports of fluorspar to the United States and 1,595 short tons were received during the last quarter of 1936. Moreover, during the 3 months from January to March 1937 imports from France totaled 4,949 short tons, indicating that France may become one of the chief importing countries in 1937.

Presumably the fluorspar being imported from France is from the same deposits that formerly furnished supplies, as the exported fluorspar is loaded at the port of San Raphael. The deposits are in the eastern end of the Department of Var near the French Riviera sea-coast, where three mines—Font Sante, Garot, and Les Adrets, about 9 to 15 miles north of Frejus—were developed and put in operation about August 1925, producing an aggregate of 100 tons a day. The output of the mines is taken to Frejus by trucks, and that for export is shipped to the port of San Raphael by rail.

Germany.—The United States continues to be the largest export outlet for German fluorspar, taking 9,095 metric tons in 1935.⁴ Czechoslovakia took 5,582 tons, Poland 4,138 tons, Austria 3,576 tons, and Sweden 3,126 tons. Germany's total exports were 31,425 tons in 1935, 31,756 tons in 1934, and 24,907 tons in 1933.

Fluorspar production in Germany comes from 26 mines which employ a total of 708 persons. The output increased from 70,045 metric tons in 1934 to 98,414 in 1935. Domestic consumption has advanced sharply the last few years because of increased metallurgical and general manufacturing activities in Germany. Probably 60 percent of the total consumption is for fluxing.

Union of South Africa.—According to the Department of Mines⁵ of the Union of South Africa:

A flotation plant has recently been erected with a view to producing fluorspar of about 200-mesh and of the following specifications: Calcium fluoride, 98 percent minimum; silica, 1 percent maximum; and calcium carbonate, 1 percent maximum. The lump spar at present being exported is of the same specifications.

Another producer has erected a small plant and in addition to lump spar can supply ground spar containing calcium fluoride not below 90 percent, maximum CaCO_3 , 1 percent, silica 4 percent, water under 0.25 percent. The ground spar is supplied in the following mesh per linear inch—100-mesh, 85 percent; 150-mesh, 80 percent; 200-mesh, 70 percent.

Newfoundland.—The deposits of fluorspar in the Districts of Burin East and Burin West, Newfoundland, at which mining was begun in 1933, yielded about 10,000 short tons of fluorspar in 1936, and production of 17,000 tons is contemplated for 1937. Shipments in 1936 totaled 9,368 short tons, of which 1,822 tons of acid grade and 2,358 tons of fluxing grade went to consumers in the United States, 2,007 tons of special-grade lump (93 to 95 percent CaF_2) to Ontario, and 3,181 tons of fluxing grade to Nova Scotia. In 1935 production was 6,500 short tons and shipments were 4,500 tons, all of which went to Ontario and Nova Scotia.

U. S. S. R. (Russia).—It is reported⁶ that an extensive and high-grade deposit of fluorspar near Amderma (an Arctic Ocean port with 2,000 inhabitants) is being developed. During 1934, 9,000 metric

⁴ Jeslen, W. S., consular clerk, Frankfurt-am-Main, Germany, Oct. 28, 1936.

⁵ Department of Mines, Union of South Africa, Pretoria, Industrial Minerals: Quarterly Inf. Circ., August 1936, p. 23.

⁶ *Investia*, Sept. 27, 1935.

tons of fluorspar were mined, and a daily output of 400 tons is contemplated for a concentrating plant. Fresh water is difficult to obtain, so sea water may have to be used.

According to the publication, Socialistic Construction of the U. S. S. R., production of fluorspar in Russia was 49,100 metric tons in 1935 and 27,000 in 1934.

WORLD PRODUCTION

CRYOLITE

Cryolite occurs in commercial quantity and is mined at only one place—Ivigtut, Greenland. Most of the purified cryolite is used in the metallurgy of aluminum and in making opaque glass, and smaller quantities are used in enamels and glazes. Considerable ground cryolite is used in insecticides. Although finely divided cryolite resulting from the purification process has been so used for many years, an efficient method of grinding cryolite to a fineness that would permit its use for insecticides was discovered recently.

Gibbs⁷ has described the mine at Ivigtut, grades of ore produced, methods of processing and purification, and various uses of cryolite. According to Gibbs:

* * * The mine at Ivigtut is owned by the Danish State, and the mining concession belongs to the A/S Kryolith Mine og Handels Selskabet, Copenhagen. This firm divides all the raw material between the Pennsylvania Salt Manufacturing Co. of Philadelphia, which has the North American rights; and the Oresunds Chemiske Fabriker, Kommanditselskabe, ved C. F. Jarl, Copenhagen, which

⁷ Gibbs, Arthur E. (technical director, Pennsylvania Salt Manufacturing Co.), Cryolite as a Chemical Raw Material: Chem. Ind., vol. 38, May 1936, pp. 471-476.

controls the manufacture and sale in the rest of the world. * * * In 1865 the Danish company made a contract with the Pennsylvania Salt Manufacturing Co. for two-thirds of all the cryolite produced, and a plant was erected by the Salt company at Natrona, near Pittsburgh, for the refinement of the cryolite. * * *

The Greenland deposit lies on the shore and under a fjord, the open pit being separated from the water by a bank some 50 feet wide. The cryolite mine itself consists of slopes operating from the bottom of an open quarry, about 500 feet long running northeast to southwest. The north end is 60 feet wide, and the pit widens to 160 feet at the other end with a depth of 150 feet. At the northwest side of the pit an arm of cryolite extends out toward the fjord, and this is reported as the portion of the deposit now being worked.

Ivigtut and the surrounding plateau is underlain with granitic and hornblendic gneisses, probably of the pre-Cambrian era. The gneisses are cut by numerous dikes of diabase. The cryolite associated with much pegmatitic material lies entirely within a small intrusive mass of porphyritic granite, a pink formation of quartz, orthoclase phenocrysts, and biotite, which appears to be of the mother rock of the fluoride deposit.

Along the northwest wall of the quarry some green altered granite is enclosed in the cryolite. This mass consists mostly of quartz and sericite (a hydrous iron aluminum silicate containing some fluorine). At the bottom of the pit are ledges of green sericitized granite. Associated minerals led to the assumption that this cryolite deposit was an intrusive igneous mass rather than one formed by strictly water deposition, as in the case of several small deposits in Russia and in the western part of the United States.

At the mine in Greenland, a large part of the associated nonfluoride minerals are culled out. The impurities found in the cryolite ore as delivered to the Pennsylvania Salt Manufacturing Co.'s purification plant at Natrona fall into three classes: Fractions which separate out of the molten magma; products of partial interaction between the native rock and the fluoride; and products of substitution within the mass brought about by circulating waters. * * *

Due to the variety of impurities in the ore, several methods of purification have been developed. First the crude ore is screened to get rid of the very fine material in which the iron has oxidized and permanently discolored the cryolite. Then hand picking removes the fluor spar, topaz, and as much of the siderite as is free. The next stage is crushing all through $\frac{1}{4}$ -inch mesh, after which the mineral is passed on continuous rubber belts under high-power magnets which remove the magnetic impurities including siderite and part of the pyrite. Following the magnets the ore is separated into two sizes (the coarser of which passes over two types of jigs) to remove galena and pyrite in the first and silica, hagemannite, thomsonolite, and other minerals in the second. The finer sizes pass over Willfley tables and then over jigs for removal of silica, etc. After drying and further magnetic treatment, the two sizes are remixed and ground with porcelain balls in a porcelain-lined mill. An air-separator system insures a fineness in the finished product of at least 99 percent through 150-mesh and 90 percent through 300-mesh. * * *

Imports.—The following table shows imports of cryolite into the United States in 1935 and 1936 by countries. As cryolite is mined only in Greenland, it is evident that importations credited to countries other than Greenland include artificial cryolite and reexports of natural cryolite.

Cryolite imported for consumption in the United States, 1935-36, by sources

The feldspar industry broke all previous production records in 1936. The output of crude spar in the United States rose to 244,726 long tons, an increase of 29 percent over the previous year and 16 percent more than the record established in 1928. The value of the crude feldspar produced in 1936 was \$1,303,090, or 30 percent more than in the preceding year.

FIGURE 109.—Trends in production and value of crude feldspar in the United States, 1910-36.

The glass industry was chiefly responsible for this large expansion. The production of glass containers and illuminating glassware increased 20 percent over 1935. The relatively larger amount of feldspar used in the manufacture of glass has contributed in large degree to the recovery of the industry. A few years ago the glass industry took less than a third of the total feldspar consumed, but it now takes well over half of the total. Other consuming industries likewise improved in 1936. The potters bought more feldspar and, due to the sharp increase in residential building, the demand for enamel and sanitary ware increased greatly.

The average value per long ton of domestic crude spar in 1936 was \$5.32, only slightly higher than the value in 1935, when the average was \$5.30 per ton.

The increase in production of crude spar in 1936 was shared by all the producing States except Maine and Pennsylvania. New Hampshire had the largest percentage gain (71 percent), followed by California (56 percent), South Dakota (45 percent), and Virginia (38 percent). North Carolina, the largest producing State, registered the largest absolute gain in output, 19,984 tons, although this was only 24 percent more than in 1935. In Maine production declined 4 percent.

South Dakota attained second place among producing States in 1936. New Hampshire ranked third, exceeding Colorado by a small margin.

Sales of ground feldspar by merchant mills in 1936 amounted to 236,890 short tons valued at \$3,154,853, more than 18 percent greater tonnage and value than in 1935. This is a new record and is all the more remarkable in view of changing markets, more exacting standards of production and use, and increasing competition from other mineral raw materials.

The total sales of ground spar include 14,764 short tons prepared from crude spar imported from Canada. Included, also, in the total is a substantial tonnage of so-called "Carolina stone", a domestic synthetic product used much the same as natural Cornwall stone, a kaolinized feldspar. This material is covered by United States Patent 2020407.

Markets.—As feldspar is used extensively in the manufacture of enamel and sanitary ware, the industry shared in the increased activity in building construction in 1936. The output of bathroom accessories rose to 7,192,807 pieces in 1936, a gain of 143 percent over the 2,964,820 pieces reported produced in 1935. The value of shipments of porcelain-enamelled flatware was 27 percent higher than in 1935, and sales of electric refrigerators for household use increased 30 percent. Sales of electrical porcelain likewise increased sharply, shipments of

special and standard porcelain advancing 36 and 29 percent, respectively.

In the glass industry, now by far the largest single market, ground feldspar is valued chiefly for its alumina content, although the potash and soda likewise are useful additions to the batch. Glass-container shipments in 1936 increased 21 percent compared with 1935, and output of illuminating glassware rose 20 percent, approximately the same increase as for total sales of ground spar by merchant mills. No data are available on production of opaque structural glass, tile, or pottery—also important outlets for feldspar.

In 1936, sales of ground feldspar were distributed by industries as follows: Glass, 51.4 percent; pottery, 32.3 percent; enamel and sanitary ware, 10.0 percent; brick and tile, 2.6 percent; electrical insulators and other porcelain, 2.1 percent; other ceramic uses, 0.8 percent; scouring soaps and abrasives, 0.6 percent, other uses (chiefly for abrasive wheel binder), 0.2 percent. The distribution in 1935 was almost the same, but only a few years ago the glass industry accounted for only 30 percent, general ceramic uses took 15 percent, electrical porcelain 13 percent, tile 11 percent, sanitary ware 9 percent, enamel 9 percent, soaps and abrasives 7 percent, and miscellaneous uses 6 percent.

¹ Data for 1934 cover 73 percent of the total ground spar sold by merchant mills in the United States; data by uses not available for the other 27 percent in that year. Distribution shown for 1935 and 1936 is for total sales.

Capacity.—Maintenance of a productive capacity considerably in excess of current demand has been characteristic of the feldspar-grinding industry for many years. To determine the present capacity of the industry, the Bureau requested the producers of ground spar to report the tonnage of ground feldspar that could have been produced during 1936, working the usual number of hours a day, assuming a continuous demand, and allowing for unavoidable shut-downs for repairs or other unforeseen delays. Mills producing 208,327 short tons, about 88 percent of the total ground spar in 1936, reported an aggregate capacity of 467,850 tons, which would indicate an approximate total capacity of grinding equipment in the industry of 531,000 short tons. This figure is computed from data of active mills only, processing both domestic and Canadian spar.

Prices.—According to Engineering and Mining Journal Metal and Mineral Markets, prices on all grades of feldspar quoted remained at the same levels throughout 1936. Prices on North Carolina grades were: Potash and soda spar, 200-mesh, f. o. b. North Carolina, \$17 and \$19 per ton respectively; granular glass spar, 20-mesh, f. o. b. mine, \$12.50 per ton; and semigranular spar, \$11.75. Maine white potash spar, 200-mesh, and Virginia No. 1, 200-mesh, were quoted at \$17 per ton. Quotations on Virginia spar No. 1, 230-mesh, were

unchanged at \$18 per ton. Quoted prices of other Virginia spars follow: No. 17, glassmakers' \$11.75 per ton; No. 18, \$12.50, and enamellers' spar, \$14 to \$16, f. o. b. Virginia.

The average realization on all sales of ground feldspar by merchant-mill operators rose from \$13.29 in 1935 to \$13.32 in 1936.

Nepheline syenite.—During 1936, a new competitor arose in the form of nepheline syenite. Trial shipments of this material have been imported from Canada, and some of the earlier shipments, particularly those from Bancroft, occasionally ran rather high in iron. Now, however, production comes from Blue Mountain, Methuen Township, where a large, uniform deposit is being prepared for large-scale production. The material is crushed and cleaned magnetically at Lakefield, Ontario, the shipping point. Plans have been drawn for the erection of a crushing and screening plant in northern New York State. At present a duty of 30 percent ad valorem, or approximately \$3 a ton, is levied on imports of the prepared material, which is ground to pass 28-mesh (13 percent through 200-mesh) for use in the glass industry. The material as mined carries about 1 percent iron oxides; but these are present mainly as magnetite, and after treatment in magnetic separators the typical analysis is as follows: SiO_2 , 59.30; Al_2O_3 , 24.70; Fe_2O_3 , 0.05; TiO_2 , 0.01; CaO , 0.27; MgO , 0.02; Na_2O , 9.91; K_2O , 5.10; and loss, 0.44.

Ordinary feldspar seldom contains over 18 percent alumina, and even South Dakota spar rarely exceeds about 20 percent. Nepheline syenite, however, carries 24 percent alumina and also contains a slightly higher total amount of alkalis. It is sold in Canada at \$10 a ton and is offered at \$18.38, delivered at glass works in western Pennsylvania and Ohio.

As a result of extensive tests on syenite in semivitreous ware, Koenig states¹ that direct substitution of syenite for feldspar produced increased vitrification. Warpage was definitely less and firing shrinkage slightly less for syenite bodies, while modulus of rupture and modulus of elasticity were about the same. The vitrification range of the syenite bodies compared favorably with that of a feldspar body. Syenite bodies had a high coefficient of expansion. A glaze of standard formula containing syenite gave promising results.

Other competitive products.—Another substitute for feldspar may be available soon in the form of a byproduct of certain chemical-manufacturing operations. Preliminary samples indicate the possibility of maintaining a product with the composition of a synthetic sodium-aluminum silicate with over 33 percent alumina. Reports from Barre, Vt.,² state that porcelain has been produced experimentally from pulverized or waste granite and china clay. Froth flotation has been suggested for removal of undesirable mica and iron.

Another mineral definitely competitive with feldspar in certain of its uses is spodumene, a lithium aluminosilicate abundant in South Dakota, North Carolina, and Maine. The United States Bureau of Mines recently investigated the possibilities of its use in the ceramic and other industries. Two lines of approach have given satisfactory

¹ Koenig, O. J., Use of Syenite in Semivitreous Ware. I. (a) Physical Properties of Bisques, and (b) A Glaze Containing Syenite: Jour. Am. Ceram. Soc., 19, 1936 pp. 295-8; Chem. Abs., vol. 30, no. 22, Nov. 20, 1936, p. 8547.

² Pit and Quarry, vol. 28, no. 5, November 1936, p. 29.

results—flotation concentration³ and disintegration by heat. Hitherto, the expansive properties of spodumene at working temperatures have prevented its use, especially in pottery. Under the latter process, beta-spodumene, the easily disintegrated chalky white mass formed by the heating to which the matrix mineral is subjected, has already been expanded. Its uses, aside from pottery manufacture, include production of lithium salts, storage batteries, and special types of extremely tough glass.⁴

Some displacement of feldspar may accompany the larger use of pyrophyllite and magnesium talc, particularly in the manufacture of wall tile. The substantial increase in production of wall tile, however, more than offset any such quantitative displacement in 1936. The Vitrefrax Corporation, Los Angeles, Calif., is mining trachites near Mojave, Calif., to completely replace feldspar and partly replace china clay and flint in porcelain bodies. An approximate analysis of this material shows that it contains about 45 percent flint, 43 percent feldspar, and 12 percent china-clay equivalents; it is said to produce a superior product.

DEVELOPMENTS IN THE INDUSTRY

The National Feldspar Association, an organization comprising most of the feldspar producers in the industry, with offices at 19 West Forty-fourth Street, New York, N. Y., has been issuing a monthly statistical service covering shipments of ground feldspar and deliveries to mills of crudespar based on periodic reports from members. The feldspar industry is making rapid strides in technologic research and has greatly improved the uniformity of its product and extended the variety of its grades, each of which is available in a number of different grindings. A summary of the cooperative research conducted under the auspices of the association is soon to be released.

The Feldspar Miners Association, representing producers of between 75 and 80 percent of the feldspar output of North Carolina and Virginia, has been organized at Spruce Pine, N. C. One of the main objectives of the Association is to maintain uniform wages and hours in conformity with agreements in effect since the abolition of the N. R. A.⁵

The United States Bureau of Mines and the Ceramic Research Division of the Tennessee Valley Authority, in cooperation with producers in the Spruce Pine district, North Carolina, have been investigating the possible use of lower-grade spars in the preparation of a high-grade finished product.⁶ Tests of new methods of processing indicate the possibility of reducing quarrying and refining costs.

Company developments.—During 1936 the Consolidated Feldspar Corporation completed extensive improvements to its plant at Erwin, Tenn., involving crushing, screening, and dust-collecting equipment and new magnetic separators for reducing the iron content of high-grade spar. The Consolidated Feldspar Corporation also has under construction a new mill for processing feldspar at Canon City, Colo., at an expected cost of about \$100,000. This firm is reported to be

⁶ *Rock Products*, vol. 39, no. 7, July 1936, p. 33.

considering the erection of a crushing and treating plant for feldspar in Baltimore, Md., also at an estimated cost of about \$100,000.⁷

The North Carolina Feldspar Corporation has been operating a new grinding mill at Erwin, Tenn., since the latter part of 1935, the major equipment including a Hardinge conical mill, a 14-foot Gayco separator, and a Jeffrey-Taylor vibrating screen.⁸ The North State Feldspar Corporation, with plant at Micaville, N. C., discontinued business early in 1936.

The F. E. Schundler Feldspar Co., affiliated with the F. E. Schundler Co., which for some years has been grinding spar at Joliet, Ill., erected a new grinding plant at Custer, S. Dak., which operated during the last 2 months of 1936. In addition to the new mill being erected by the Consolidated Feldspar Corporation in Colorado, the Colorado Feldspar Co. has installed machinery and is planning to start grinding spar at its new \$100,000 plant at Canon City early in 1937. Crude spar is to be obtained from Fremont County.⁹ The Western Feldspar Milling Co., Denver, Colo., has built an addition to house equipment for its glass-spar operations. New equipment also is to be installed for treating pottery spar.¹⁰

In the East, there have been several new developments. The Seaboard Minerals Corporation, 52 William Street, New York, N. Y., began operating its plant at Cold River, N. H., in 1935. The Ceramic Feldspar Co., Bath, Maine, took over the plant formerly known as the Cummings Feldspar Co., and started grinding operations early in 1936. The Trenton Flint & Spar Co., Trenton, N. J., with grinding plant at Cathance, Maine, is reported to be out of business. The White Hill Mineral Co., Gouverneur, N. Y., has reopened the mines and processing plant formerly operated by the Green Hill Mining Co. of Gouverneur. The grinding mill is reported to have a daily capacity of about 75 tons.¹¹

REVIEW OF INDUSTRY BY STATES

The term "crude feldspar" is applied to lump spar shipped from the mine or quarry, contrasted with ground spar, the finished product of crushing and pulverizing equipment. Statistics of production are presented separately for crude and ground spar; in accordance with the usual practice in the industry, the crude is reported in long tons of 2,240 pounds and the ground in short tons of 2,000 pounds.

Normally, the tonnage of ground spar produced from domestic crude is about 87 percent of the crude-spar output, the remaining 13 percent representing spar sold for purposes that do not require fine grinding and that lost or discarded during the grinding process. In spite of an 18 percent increase in output of ground spar in 1936, sales of domestic ground feldspar did not advance as sharply as crude, indicating substantial accumulation of crude stocks.

Crude feldspar.—Production of crude feldspar in the United States in 1936 totaled 244,726 long tons valued at \$1,303,090, an increase of 29 percent in tonnage and 30 percent in value over 1935. The tonnage exceeded the output of 1928, the previous peak year, by 16 percent. The average realization for crude spar at the mine increased slightly,

⁷ Pit and Quarry, vol. 28, no. 11, May 1936, p. 46.

⁸ Pit and Quarry, vol. 29, no. 2, Aug. 1936, p. 38.

⁹ Pit and Quarry, vol. 28, no. 8, February 1937, p. 46.

¹⁰ Rock Products, vol. 40, no. 1, January 1937, p. 74.

¹¹ Pit and Quarry, vol. 28, no. 10, April 1936, p. 32.

from \$5.30 a ton in 1935 to \$5.32 in 1936. Although in 1936 the spread between high and low values per ton was somewhat less than in other years, sales realizations per long ton ranged from \$2.46 to \$10 for individual producers. In New England the average value ranged from \$4 to \$8.68; for New York, Pennsylvania, and Virginia, from \$3.38 to \$7.28; for North Carolina, from \$4 to \$8.19; and for the Western States, from \$2.46 to \$10.

Average values for the larger producing States are much more illuminating and indicate clearly the difference between sales realizations in the Western States and in the New England and Southern Appalachian regions. Thus, the average values per long ton of crude spar produced in Colorado and South Dakota in 1936 were \$3.95 and \$3.23, respectively, while those for New Hampshire and Maine were \$5.95 and \$5.57. In the Southern Appalachian district average realization per ton was \$5.77 in North Carolina and \$5.61 in Virginia.

Crude feldspar sold or used by producers in the United States, 1932-36

1934.....	154,188	853,136	5.53				

Twelve States produced crude feldspar in 1936—the same States that produced spar in 1935, except Nevada. North Carolina, the largest producer of crude spar, increased production from 82,499 long tons in 1935 to 102,393 tons in 1936, or nearly 20,000 tons (24 percent) more than in the previous year. South Dakota rose to second place with 32,144 tons, and New Hampshire's output totaled 26,494 tons, 71 percent more than in 1935. Colorado dropped into fourth place, with a crude production of 25,806 long tons. The output of spar in Virginia advanced to 20,459 tons in 1936. Maine reported production of 16,392 tons, a small decrease from 1935. The other producing States in 1936, in order of importance, were New York, California, Connecticut, Arizona, Maryland, and Pennsylvania.

Ground feldspar.—Feldspar consumed for virtually all industrial purposes is finely ground before use. Even spar used for facing cement blocks and covering prepared roofing is crushed and roughly sized by screening. A canvass of all consumers of feldspar to determine quantities used by them has not been practicable. However, all known merchant mills or grinders—that is, those that mine, quarry, or purchase crude spar and grind it for sale to other establishments—have been canvassed in recent years.

Sales of ground feldspar by merchant mills in 1936 advanced to 236,890 short tons valued at \$3,154,853, the highest tonnage sold in any year. Production was 18 percent greater than in 1935, and the value of the output increased 19 percent. Thirty mills operated in 1936; these were owned by 23 producing companies in 14 States. Spar of domestic origin was ground by 26 mills and spar imported from Canada was ground by 4 mills. Domestic spar accounted for 94 percent of the total quantity processed compared with about 95 percent in both 1935 and 1934.

¹ Does not include potters or others who grind for consumption in their own plants.

The average value of the ground feldspar produced from domestic crude in 1936 was \$12.99 per short ton, slightly less than for 1935. The average value for the various States ranged from \$7.37 to \$20.54 per ton. The realization figures for Colorado and South Dakota in 1936 were \$7.37 and \$9.66 per ton, respectively, considerably under the average values for certain of the larger eastern feldspar-grinding States. Average sales realizations in the Eastern States were as follows: Maine, \$14.65 per ton; New Jersey, \$19.88; and North Carolina-Tennessee, \$13.53. Ground spar produced from Canadian crude in 1936 averaged \$18.31 per ton, slightly less than in 1935.

North Carolina remained the largest producer of ground spar, followed by Tennessee, Colorado, and South Dakota. These four States in 1936 produced 59 percent of the total spar ground (North Carolina-Tennessee, 36 percent; Colorado, 12 percent; and South Dakota, 11 percent). The other larger producing States, in order of importance, were New York, Maine, New Hampshire, New Jersey, and Virginia; Illinois, California, Ohio, Arizona, and Minnesota produced smaller amounts.

Production of ground spar in 1936 increased in all States except Minnesota, in which the output declined slightly; and Virginia, where output was virtually the same as in 1935. Production in North Carolina-Tennessee, South Dakota, Colorado, Maine, New Hampshire, New Jersey, and New York increased substantially compared

with 1935. The tonnage reported by most of the States that normally produce smaller amounts also showed large proportional increases.

¹ Does not include potters or others who grind for consumption in their own plants.

² Included under "Undistributed."

IMPORTS ¹²

Imports of crude feldspar, which amounted to 8,937 long tons valued at \$56,175 in 1935, rose to 10,786 long tons valued at \$68,198 in 1936. This imported spar was largely Canadian in origin, United Kingdom supplying only 154 tons valued at \$1,039. Ground spar imported from Canada totaled 33 tons valued at \$301, and 99 tons valued at \$975 were imported from the United Kingdom.

Imports of unmanufactured Cornwall stone in 1936 more than doubled 1935 receipts, totaling 2,061 long tons valued at \$18,402, compared with 817 tons valued at \$7,449 in 1935. Imports of ground Cornwall stone rose to 357 tons valued at \$4,730 in 1936, compared with 242 tons valued at \$3,180 in 1935. All imports of both crude and ground material in 1936 originated in the United Kingdom. More complete data on imports of Cornwall stone appear in Minerals Yearbook, 1934, page 1003.

Feldspar imported for consumption in the United States, 1931-36

¹² Figures on imports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

WORLD PRODUCTION

Feldspar is produced chiefly in the United States, Sweden, Norway, China, Canada, and probably Czechoslovakia, although no official data on the Czechoslovak output are available. The greater part of the Canadian output of crude spar is shipped to the United States for grinding.

Available figures on world production of feldspar follow:

World production of feldspar, 1932-36, by countries, in metric tons

Exports.....	1367		

The United States, with several hundred factories manufacturing asbestos products, leads all countries in output of these important commodities. In 1936, as in previous years, domestic deposits furnished only a small percentage of the requirements of raw asbestos. Small quantities of high-grade chrysotile of spinning quality are obtained in Arizona, and an increasing tonnage of short-fiber chrysotile is produced in Vermont. Small quantities of nonspinning anthophyllite (amphibole asbestos) are produced in Maryland, North Carolina, and Montana. As indicated in the table of salient statistics that follows, domestic sources furnished only 4.4 percent of the consumption in 1936. Foreign supplies were obtained chiefly from Canada, U. S. S. R. (Russia), and British Africa.

The varieties, properties, history, production, occurrences throughout the world, uses, mining and milling methods, classification, and marketing of asbestos and the manufacture of asbestos products are covered in some detail in Bureau of Mines Bulletin 403, entitled "Asbestos", published in 1937.

Domestic production amounted to 10,845 short tons in 1936 compared with 9,415 tons in 1935, an increase of 15.2 percent. Asbestos sold or used by producers in 1936 (11,012 tons valued at \$309,994) increased 23.5 percent in quantity and 5.8 percent in value over 1935. Compared with 1935 the apparent consumption of asbestos in the United States in 1936 increased 43.6 percent in quantity and 41.2 percent in value. The value of exports of asbestos products increased 9.6 percent.

¹ Bureau of Mines not at liberty to publish figures separately for chrysotile and amphibole.

² Figures not available.

Consumption trends.—The following table of apparent consumption of raw asbestos, value of products manufactured, and value of products exported shows major trends in recent years. Apparent consumption is determined by adding imports (unmanufactured) to domestic asbestos sold or used by producers and subtracting exports (unmanufactured). No data are available to make adjustments for variation in consumers' stocks.

Raw asbestos consumed in the United States and asbestos products manufactured in and exported from the United States, 1932-36

Year	Raw asbestos— apparent consumption	Asbestos products		Year	Raw asbestos— apparent consumption	Asbestos products	
		Manufactured ¹ (value)	Exported ² (value)			Manufactured ¹ (value)	Exported ² (value)

1934.....	123,752	(¹)	2,142,514				

¹ Figures of Bureau of the Census (collected biennially for odd years) include value of certain gaskets packing, and similar products in which little asbestos was employed.

² Compiled from the records of the Bureau of Foreign and Domestic Commerce.

The volume of asbestos consumption depends primarily on two great industries, automobile manufacture and the building trades. Large quantities of asbestos are used for making brake bands and clutch facings for automobiles, and in the building industries asbestos is employed for heat insulation or as a constituent of asbestos-cement products, such as roofing and wallboard. Figure 110 illustrates trends in automobile and building industries and in consumption of asbestos during recent years.

Market conditions.—The demand for asbestos improved steadily throughout the year. It was stimulated by a moderate increase in building activity and by a decided upturn in automobile production.

FIGURE 110.—Asbestos consumption compared with automobile production and building construction, 1927-36. Unlike units are reduced to percentages of the 1923-25 average. Statistics of asbestos are from the Bureau of Mines, automobiles from the Bureau of the Census, and building contracts from the Federal Reserve Board.

Prices.—According to quotations in Metal and Mineral Markets the prices of some grades of Canadian fiber were advanced in March 1936, after which prices per ton were constant throughout the year as follows: Crude No. 1, \$550; Crude No. 2, \$200-225; spinning fibers, \$90-150; magnesia and compressed sheet fibers, \$100-110; shingle stock, \$45-75; paper stock, \$32.50-37.50; cement stock, \$19-23; and floats, \$16-18.50.

Rhodesian Crude No. 1 was quoted at \$210 and Crude No. 2 at \$185 a ton throughout the year.

From March to December 1936, Russian Crude AA was quoted at \$475, No. 1 at \$225, No. 2 at \$190, and shingle stock at \$55.

Vermont prices were constant throughout the year: Shingle stock, \$47.50; paper stock, \$35; cement stock, \$23; and shorts, \$11-12.

Canadian prices are f. o. b. Quebec mines, tax and bags included; Rhodesian and Russian, c. i. f. New York; and Vermont prices f. o. b. mines, Vermont.

REVIEW BY STATES

Arizona.—A small tonnage of Arizona chrysotile asbestos was sold in 1936 by the Arizona Asbestos Corporation, Los Angeles, Calif.; The Bear Canyon Asbestos Co., Globe, Ariz.; and the Johns-Manville Products Corporation, New York, N. Y.

California.—A deposit of chrysotile, some of which will grade as No. 1 Crude, is reported near Chicago Park, Nevada County. No development work has been done.

Maryland.—The Powhatan Mining Corporation continued production of anthophyllite near Pylesville, Harford County, and prepared it for use in chemical filters.

Montana.—The Karstolite Co. mined anthophyllite near Gallatin Gateway, Gallatin County, and sold it prepared for wall and ceiling insulation.

North Carolina.—The National Asbestos Co. produced a small tonnage of anthophyllite at Minneapolis, Avery County. It was processed and sold for use in home insulation similar to that of mineral wool.

Oregon.—Samples of chrysotile asbestos of good quality, said to have been obtained in Malheur County, were submitted to the Bureau of Mines. No information is available as to the location or extent of the deposit.

Vermont.—Since the Ruberoid Co. assumed control of the asbestos property near Eden, Lamoille County, the mill has been so enlarged and improved that its output will be doubled. With new equipment "floats" will be recovered, and a special grade of fiber for molded brake linings will be prepared. The operating firm is the Vermont Asbestos Corporation, 500 Fifth Avenue, New York, N. Y.

FOREIGN TRADE ¹

Imports.—The following table shows imports of unmanufactured asbestos into the United States in 1935 and 1936. Of the crude fibers imported, Canada furnished only about 29 percent and Africa about 70 percent. The importation of nearly 17,000 tons of mill fiber from Hungary is noteworthy. As there is no record of production in Hungary the material doubtless originated in some other country, probably in the U. S. S. R. (Russia).

WORLD PRODUCTION

Asbestos production is centered chiefly in Quebec (Canada), Southern Rhodesia, the Union of South Africa, the U. S. S. R. (Russia), United States, and Cyprus. Relatively small quantities are produced in Italy, Australia, Finland, and several other countries. The following table shows world production, by countries, from 1932 to 1936, insofar as figures are available.

World production of asbestos, 1932-36, by countries, in metric tons ¹

² Rail and river shipments.

³ Data not available.

⁴ Exclusive of sand and gravel, production of which is reported as follows: 1932, 3,151 tons; 1933, 5,847 tons; 1934, 4,238 tons; 1935, 2,744 tons; 1936, 2,815 tons.

⁵ Exports.

⁶ Approximate production.

CANADA

The strong upturn in production that characterized the Canadian asbestos industry in 1935 was continued in 1936. Output increased 43 percent in quantity and 41 percent in value over that of 1935. The entire production was from the eastern townships of the Province of Quebec. The following table shows production in 1936 as published in the Preliminary Report on the Mineral Production of Canada in 1936, issued by the Dominion Bureau of Statistics.

AFRICA

Rhodesia.—Production of asbestos in Southern Rhodesia in 1936 was the highest on record, exceeding that of the former peak year, 1929, by 32 percent. The value, however, was 29.5 percent lower than in 1929. The lower average value per ton during recent years indicates that a larger proportion of lower grades are now demanded, particularly for the expanding asbestos-cement products industries of Europe. That prosperity has returned is shown by the fact that Turner & Newall, Ltd., the principal producer in Rhodesia and the largest manufacturer of asbestos products in the British Empire, paid a dividend of 17½ percent on the ordinary stock for the year ended September 30, 1936, compared with 12½ percent for 1934-35 and 10 percent for 1933-34. The following table shows Rhodesian production from 1927 to 1936.

Asbestos produced in Rhodesia, 1927-36

Year	Short tons	Value	Year	Short tons	Value
1927-31 (average).....	35,515	£881,702	1934.....	32,214	£402,745
1932.....	15,766	197,092	1935.....	42,598	646,658
1933.....	30,182	555,993	1936.....	56,346	836,469

Union of South Africa.—Asbestos production in the Union of South Africa in 1936 increased 7.9 percent over that of 1935 but was still 25.5 percent below the peak production of 1929. The following table shows the output from 1927 to 1936.

Asbestos produced in the Union of South Africa, 1927-36, by sources

Year	Short tons				Total value
	Transvaal	Cape Province	Natal	Total

1935.....	20,379	2,420	-----	22,799	226,881
1936.....	21,504	2,925	-----	24,429	1 330,375

¹ Value of local sales plus value of exports.

The Union of South Africa is unique in that it produces four different kinds of asbestos. Because of a change in the method of tabulating returns the value for 1936 is not comparable with that of previous years. The following table shows the tonnage of each variety produced in the Transvaal and Cape Provinces from 1932 to 1936.

Asbestos produced in the Union of South Africa, 1932-36, by varieties and sources, in short tons

¹ Data from Quarterly Information Circulars, Union of South Africa, Department of Mines.

² Includes 73 tons anthophyllite.

U. S. S. R. (RUSSIA)

As indicated in the following table Russian production has made substantial gains since 1932. Exports have not increased proportionally, a condition that reflects the growing importance of the asbestos-products manufacturing industries in that country. In 1935 nearly three-fourths of the tonnage produced was used in domestic factories.

Production and exports of Russian asbestos, 1932-36, in metric tons

² Official estimate.

CYPRUS

Tunnel Asbestos Cement, Ltd., a subsidiary of the Tunnel Portland Cement Co. of West Thurrock, England, continued production of short-fiber chrysotile at Amiandos. A substantial gain in production is recorded for 1936. The following table, compiled mainly from the Annual Report of the Inspector of Mines and Labour, shows exports during recent years. The entire production is exported.

Asbestos exported from Cyprus, 1932-36

Year	Long tons	Value	Year	Long tons	Value
1932.....	1,600	£27,214	1935.....	7,513	£50,174
1933.....	4,567	1 44,088	1936.....	9,506	80,343
1934.....	7,590	1 73,562			

¹ Reported by Cyprus & General Asbestos Co., Ltd.

OTHER COUNTRIES

Australia produces a small quantity of asbestos; production centers particularly in the Roebourne district of Western Australia. Finland produces a considerable quantity of short fiber annually, and Italy is a steady producer on a small scale. Production has been reported at times in China, India, Czechoslovakia, France, Bulgaria, and Austria.

BARITE AND BARIUM PRODUCTS¹

The crude barite industry of the United States in 1936 was characterized by increases in quantity of crude barite mined; quantity and value of sales; new supply, of which domestic shippers furnished 89 percent; and consumption. Imports of crude barite decreased in quantity, total value, and average value. Sales of barium products decreased in total quantity and value, and imports of barium products decreased in quantity but increased in value. The total quantity and value of exports of lithopone increased.

FIGURE 111.—Trends in domestic sales, imports, consumption, and average value f. o. b. mines of crude barite, 1921-36.

Figure 111 shows recent trends in sales of crude barite from domestic mines, imports, consumption, and average value per ton in the United States.

Salient statistics covering barite and the leading barium products are summarized for recent years in the following table.

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

¹ F. o. b. mine shipping point.² Declared value f. o. b. foreign market.³ Barite sold or used by producers plus imports.**CRUDE BARITE**

Production.—The production of crude barite in the United States comes from three areas—the southern, midwestern, and Pacific. About four-fifths of the crude produced in the southern area is shipped to eastern and the rest to midwestern markets. A little ground barite is produced in the local mills. The midwestern area, of which Missouri is the leading producing State, supplies midwestern consumers; only a small part of the production reaches other markets. Production in the Pacific area in recent years has come from California, Nevada, and Arizona, and virtually all of it is consumed on the Pacific coast.

Crude barite was mined in six States in 1936, and seven in 1935; South Carolina did not appear as a producer in 1936. Producing States in 1936 were as follows: Pacific area, California and Nevada; midwestern area, Missouri; and southern area, Georgia, Tennessee, and Virginia. Mined production in 1936 totaled 274,062 short tons—55,987 tons more than in 1935.

Sales.—Sales of crude barite in 1936 totaled 283,160 short tons valued at \$1,674,631 compared with 225,111 tons valued at \$1,251,268 in 1935. All six producing States sold crude barite in 1936, Missouri (with numerous producers) leading with 160,866 short tons. In the other producing States sales in 1936 were reported by all the producers in Georgia (four), Nevada (three), and Virginia (two); in California there were three producers in 1936, but only two of them made sales; and in Tennessee only two producers reported production and sales in 1936, but sales are reported to have been made also by two other companies.

Crude barite sold or used by producers in the United States, 1935-36, by States

¹ 1935: California, Nevada, South Carolina, Tennessee, and Virginia; 1936: California, Nevada, Tennessee, and Virginia.

Prices.—Market quotations for crude barite, f. o. b. mines, from Georgia remained the same in 1936 as in 1935. The price quotations for Missouri crude (95 percent barium sulphate, less than 1 percent iron), however, ranged in 1936 from \$5.50 to \$7 per short ton compared with a slightly greater range, \$5 to \$7 per ton, in 1935. The average value f. o. b. mine shipping point for the entire United States, as calculated from values and tonnages reported by producers to the Bureau of Mines, increased from \$5.56 in 1935 to \$5.91 in 1936.

² 95 percent barium sulphate, less than 1 percent iron.

Markets for crude barite.—The markets for crude barite in the United States are three widely separated areas—the eastern, midwestern, and Pacific. The main competitive market in the East is supplied largely from imports and shipments from the Southern States. Ordinarily, less than 1 percent of the domestic barite sold in this area comes from Missouri. The midwestern market obtains most of its supply from Missouri, but about 20 percent comes from Georgia and Tennessee. The small Pacific coast demand is met with barite from mines in Nevada and California. Virtually no barite from other domestic or foreign sources enters this market.

Consumption by uses.—The barite-consuming industries of the United States used 303,449 short tons of domestic and imported barite in 1936 compared with 290,344 short tons in 1935, an increase of 13,105 tons. Changes in the distribution of this crude barite according to specified consuming industries are shown in the following table. Figure 112 shows trends in the consumption of crude barite for the principal uses in percentages of total consumption.

Crude barite consumed in the production of barium chemicals was 27 percent of the total in 1931 but subsequently decreased, comprising only 17 percent in 1935 and 1936. The percentage used for production of ground barite, which decreased from 1926 to 1931, increased to 32 percent in 1935 but fell to 28 in 1936. The percentage of crude barite consumed in the production of lithopone, the principal use, increased

to 55 percent of the total consumption in 1936 compared with 50 percent in 1935.

Crude barite (both domestic and imported) used in the manufacture of barium products in the United States, 1932-36, in short tons

Year	In manufacture of—			Total	Year	In manufacture of—			Total
	Ground barite	Lithopone	Barium chemicals			Ground barite	Lithopone	Barium chemicals

FIGURE 112.—Crude barite (domestic and imported) used in the manufacture of barium products in the United States, 1927-36, in percent of total consumption.

Figure 113 shows the relationship of the indexes of barite consumption and lithopone sales (1923-25 average=100) to industrial production, as represented by the Federal Reserve Board index of industrial production (1923-25 average=100).

Consumption by States.—Crude barite was consumed in 30 plants in 12 States in 1936, the same as in 1935. California, with 5 plants in 1936, instead of 4 as in 1935, is in the Pacific market area; Missouri with 4 plants in 1936 instead of 5 as in 1935, Illinois with 6 plants, and Kansas with 1 plant (a total of 11 plants) are in the midwestern area; and the remaining 8 States, with 14 plants, lie in the eastern area.

FIGURE 113.—Ratio of indexes of crude barite consumption and domestic lithopone sales (1923-25 average = 100) to Federal Reserve Board index of industrial production (1923-25 average = 100), 1921-36.

¹ A plant producing more than 1 product is counted only once in calculating State totals.

Foreign trade.—Total imports of crude barite, which dropped from 85,729 short tons in 1929 to 40,031 tons in 1934, increased to 47,047 tons in 1935 and again dropped in 1936 to 33,843 short tons valued at \$170,316. Imports from Germany declined to a new low of only 110 short tons, having dwindled steadily from 41,117 tons in 1931. The Netherlands was by far the leading source of crude barite imports in 1936, shipping 26,714 tons to this country, an increase of about 6,000 tons over 1935. France, with 5,040 tons, was the second largest shipper of crude barite to the United States in 1936; Italy, with 1,213 tons, ranked third. Spain furnished 15,401 tons of barite in 1935 compared with only 22 tons in 1936.

Exports of crude barite from the United States are not separately recorded.

FIGURE 114.—World production of crude barite, by countries, 1927-36

World production.—The following table shows the output of barite in various countries from 1932 to 1936, as far as statistics are available.

Germany is by far the largest producer of crude barite; most of its production comes from Prussia, although Baden, Bavaria, Saxony, and Thuringia also contribute. The United States, United Kingdom, Italy, and France also produce large quantities of barite.

Figure 114 shows graphically the output of the principal barite-producing countries from 1927 to 1936, insofar as statistics are available.

World production of barite, 1932-36, in metric tons

¹ Data not available.² Official figures which, it is reported, cover only output of mines included under the mining law.

BARIUM PRODUCTS

Sales.—Sales of ground barite, lithopone, and blanc fixe were less than in 1935. The decreases in sales of ground barite and lithopone interrupted a continuous recovery in sales of these products from the depression of 1932. The lower 1936 figure for blanc fixe, however, represents a continuation of the decline which began in 1934 following a sharp recovery from the 1932 low. Sales of artificial barium carbonate and other barium chemicals were greater in 1936 than in 1935.

Lithopone sales for floor coverings and textiles and rubber were larger in 1936 than in 1935, but other outlets took less.

Prices.—Prices for ground barite and ground witherite were the same in 1936 as in 1935. The quoted price of ground barite, \$23 per short ton f. o. b. St. Louis, has not changed for several years. Lithopone price quotations had a slightly greater range in 1936 than in 1935, as the lower limits were slightly below those of 1935 and the upper limits were the same. Quotations for barium chemicals changed little. Prices for barium carbonate, barium chloride, barium dioxide, and blanc fixe were the same in both years. Prices for barium chlorate ranged from 15½ to 17½ cents a pound in 1936 compared with 14 to 17½ cents in 1935. Quotations for barium hydrate were 5¼ to 6 cents in 1936; only a slight deviation from 5½ to 6 cents in 1935. Barium nitrate prices in 1936 ranged between 7 and 8¼ cents compared with a quotation of 8¼ cents in 1935.

Exports of lithopone in 1936 increased to 2,538 short tons valued at \$229,942, the largest quantity and value of any year since 1932. The unit value of exports of lithopone during 1936 was \$90.60, a slight decrease from the \$93.43 unit value of exports in 1935 but still above the low point of \$83.09 in 1934.

The slackened demand for new potash in world markets apparent in 1936 probably reflected absorption of stocks accumulated by consumers and speculators in 1935 at the bargain prices resulting from the German-Spanish potash war rather than an actual shrinkage in consumption of potash salts. Reports of fertilizer sales indicate an upward trend that would normally produce a parallel movement in the potash trade.

In the United States the rapidly rising curve that in 1935 pictured a 57-percent increase in producers' and importers' sales for domestic consumption, to reach an all-time high of 420,000 short tons, turned downward in 1936 to 397,000 tons. Crop restrictions, drought, and speculative resales each contributed to this result in undetermined degree. Stocks bought at bargain prices in 1935 and sold or distributed at the higher levels prevailing in 1936 were recorded in Government statistics as sales for consumption in the first instance and were unreported on their later reappearance through resale or otherwise for actual use. Analysis of export figures indicates that about 40,000 tons of this material were disposed of through export channels in 1936, but no information is available to indicate how much found its way into domestic use. Estimates of consumption in 1935 and 1936 are obviously distorted by lack of information regarding stocks in the hands of consumers and speculators that normally have little significance.

Notwithstanding a slight drop in domestic sales the value at the plant of all material sold increased \$1,975,000, evidencing the more favorable price levels that prevailed throughout 1936. The total value of imports dropped only about 2 percent, although the tonnage in terms of K_2O fell off 12 percent. The industry appears now to have emerged from the aftermath of the 1934-35 price war, and the recent course of the market indicates that stocks accumulated at that time have been nearly if not completely liquidated. The trend of fertilizer sales in the early months of 1937 indicates a continuation of the upward movement in potash consumption.

The growing use of high-analysis salts was strikingly in evidence during the year. Muriate averaging 61 percent K_2O constituted

94 percent of domestic sales, and high-grade salts averaging 56 percent made up 63 percent of imports. The use of more concentrated fertilizers effects a large saving in freight on inert materials, and the farmers are learning to apply them without injury to crops. However, domestic refiners still find it expedient to dilute part of their high-purity products to supply the slowly diminishing demand for lower-grade material. Continued educational efforts eventually may eliminate the necessity for this uneconomic practice.

Except for better prices the domestic picture was little changed from that in 1935. The plant of the American Potash & Chemical Corporation at Trona, Calif., extracting potash and other salts from the brines of Searles Lake, and the mines of the United States Potash Co. and the Potash Co. of America at Carlsbad, N. Mex., together supplied over 98 percent of American output. A few thousand tons were derived from distillery waste and cement flue dust, and insignificant amounts were contributed by cotton-boll ashes and untreated alunite. Reports that small quantities of potash were made from brines of the Salduro marsh in Utah could not be substantiated. Plants of the three principal producers were operated at full capacity, turning out high-purity muriate in quantity slightly in excess of sales.

Interruption of Spanish shipments at about midyear, following the outbreak of civil war, had little or no effect on world markets, as the Spanish quota was supplied by German members of the International Cartel. The prospect for 1937 is less assuring in this respect. Seizure and operation of the mines by the Spanish Government appear inevitable, if not already an accomplished fact. The natural sequence would be to dump the output abroad at any price obtainable to procure foreign exchange for purchase of war materials. Neutrality agreements and European political alignments offer some obstacles to this procedure.

The International Potash Cartel now includes all important producing countries except the United States and U. S. S. R. (Russia), although the Spanish members no longer control their properties. The addition of Palestine to the cartel group did not materially change relations previously adjusted by informal arrangement. U. S. S. R. now displays little interest in foreign markets, and her own need for potash so far exceeds her present capacity to produce that the home market may be expected to occupy her attention for some time to come.

Salient statistics of the domestic potash industry for 1935 and 1936 are summarized in the following table:

Salient statistics of the potash (crude and refined potash materials) industry in the United States, 1935-36

PRICES

Following the usual custom, base prices of 1935 schedules without discount carried over to April 30, 1936, the end of the 1935-36 season. Muriate was quoted at 45 cents per unit of K_2O , 30-percent manure salts at 48 cents per unit, 20-percent kainite at 55 cents per unit, sulphate at \$33.75 per ton, and sulphate of potash-magnesia at \$22.25 per ton. New schedules issued in April continued these prices through May and June. In the latter part of June new lists appeared raising base prices to 50 cents per unit for muriate, 55 cents per unit for 30-percent manure salts, \$12.00 per ton for 20-percent kainite, \$36.25 for sulphate and \$24.75 for sulphate of potash-magnesia. Seasonal discounts offered were 10 percent to July 15, 5 percent to September 30, and 2 percent to November 30. Early in July the 10-percent discount was raised to 12 percent and extended to include July 18. After November 30 prices were net list, guaranteed to and including June 30, 1937. All quotations are c. i. f. customary United States Atlantic, Gulf, and Pacific ports.

The following table, compiled by the American Potash Institute, shows average net prices for the years 1926 to 1936, inclusive, and month-by-month averages for 1936. These figures are averages of published quotations, not weighted for tonnage, the bulk of which is sold during the discount period.

December.....						

Price schedules for the season July 1, 1937, to May 31, 1938, issued in May 1937, again raise the price. Muriate is quoted at 53½ cents per unit of K_2O , 30-percent manure salt at 58½ cents per unit, 20-percent kainite at \$12.75 per ton, and sulphate of potash-magnesia at \$25.75 per ton. Discounts are 12 percent to June 30, 5 percent to September 30, and net thereafter.

CONSUMPTION AND USES

On the assumption that exports not traceable to domestic origin represented resales of previously accumulated stocks in the hands of consumers or speculators, primary sales for domestic consumption totaled 826,511 short tons equivalent to 396,466 tons of K_2O compared with 930,000 tons equivalent to 420,000 tons of K_2O in 1935. Total domestic consumption was more by an undeterminable amount than these figures indicate, since absorption of accumulated stocks in the hands of fertilizer manufacturers, normally of little significance, were important in 1936 trade. Potash consumption in recent years has been running ahead of fertilizer sales because of the growing tendency to increase the potash ratio in mixed fertilizers; 1936 fertilizer sales of 6,815,000 tons were 10 percent above 1935.

The average potash content of all material sold for domestic consumption in 1936 was 48 percent compared with 45 percent in 1935, showing the continuing shift to high-purity salt. The total of imports and sales of domestic products was 890,401 short tons of material containing 434,576 tons of potash (K_2O) valued at \$19,286,146 compared with 1,010,517 tons of material containing 466,231 tons of potash valued at \$17,506,192 in 1935. Domestic producers supplied 45 percent of the gross tonnage containing 51 percent of the potash in 1936 compared with 40 percent of the gross containing 48 percent of the potash in 1935. In terms of K_2O , domestic sales decreased about 1 percent in amount, but increased nearly 40 percent in value. Imports decreased 12 percent in amount and 2 percent in value. About 8 percent of the total potash was absorbed by the chemical industries, and 92 percent was sold for fertilizer.

In the following table the quantity and source of potash materials sold by producers and importers for agricultural use and for use in the chemical industries are shown. The total given is primary supply only, exclusive of resales, and the exports deducted to indicate domestic consumption are likewise exclusive of resale. There was little inducement for speculative purchases in 1936, and it is assumed that virtually all resales during that year came from stocks accumulated at the low point in 1935 that could be disposed of profitably on the 1936 market. About 40,000 tons of exports were derived from this source. This break-down was made possible by information, not hitherto available, supplied by the American Potash Institute.

Primary supply of potash salts in the United States in 1936, in short tons

	Bulk salts	K_2O equivalent
For agricultural use:		
Domestic sales.....	370, 539	206, 396

Exports from primary sources.....	63, 890	38, 110
Domestic consumption.....	826, 511	396, 466

PRODUCTION AND SALES

Domestic production of merchantable potash salts increased 21 percent to a new high of 431,470 short tons. The average grade of these products was 57 percent K_2O , and the total potash 247,340 tons, an increase of 28 percent over the 1935 output. Production exceeded sales by 34,780 gross tons, an excess of 9 percent. Sales decreased 10,232 tons, equivalent to 1,911 tons of potash, but the value at the plant of all products sold increased nearly 40 percent.

The total tonnage of potash materials, as reported by producers, is made up of both crude and refined salts containing varying quantities of K_2O ; to avoid duplication, however, for refined material only the final weight is included rather than the larger tonnage of crude required in its production. Hence, the domestic production of crude salts is larger than is shown in the following table, although the figure truly represents the operators' output of both crude and refined salts without duplication. To reduce different grades of salts to a common denominator, the production and sales also are calculated in terms of K_2O content. The resulting figures are reliable indicators of trends in the industry and are generally used in the trade because potash commonly is sold on the K_2O basis.

Production and sales by States and by sources cannot be given without disclosing individual output. Production and sales of potassium salts and stocks in the hands of producers for the past 5 years are summarized in the following table:

Potassium salts produced, sold, and in producers' stocks in the United States, 1932-36

Year	Production			Sales				Producers' stocks		
	Number of operators	Potassium salts (short tons)	Equivalent as potash (K_2O) (short tons)	Number of operators	Potassium salts (short tons)	Equivalent as potash (K_2O) (short tons)	Value f. o. b. plant	Number of operators	Potassium salts (short tons)	Equivalent as potash (K_2O) (short tons)
1932.....	5	143,120	61,990	5	121,390	55,620	\$2,102,590	3	41,000	28,000

GOVERNMENT ACTIVITIES

Two more patents were issued during the year covering processes developed in Bureau of Mines laboratories for the recovery of potassium salts from minerals. All patents growing out of the Bureau's work on potash recovery have been assigned to the United States.

The policy adopted in 1935 of withholding issuance of potash-prospecting permits in New Mexico to avoid overdevelopment was continued during 1936. No new permits were issued, and all permits previously issued have now expired by limitation. Three leases were applied for by permittees who had complied with the necessary requirements.

Pursuant to Senate Resolution 274, 74th Congress, 2d Session, a subcommittee of the Committee on Public Lands and Surveys undertook an investigation of all phases of the potash industry. Hearings were held, and the organization of the industry was studied. The

resolution instructed the committee to report at the next session of Congress. However, the investigation has not been completed, and it is anticipated that an interim report will be submitted and authority sought to continue the investigation another year.

The Bureau of Chemistry and Soils of the Department of Agriculture continued the study of methods of preparing suitable potash fertilizer salts from various raw materials. Reed and Clark¹ presented a paper at a meeting of the American Chemical Society describing a method of making potassium nitrate from potassium chloride and nitrogen peroxide. Potassium nitrate contains two important plant food elements and has chemical and physical properties that make its use for fertilizer advantageous, but such use has been limited by the cost of manufacture. Interest has been revived by the advent of low-cost ammonia, a possible source of nitrogen for potassium nitrate.

REVIEW BY STATES

California.—The American Potash & Chemical Corporation, 70 Pine Street, New York, operated its refinery at Trona, Calif., at near capacity throughout the year. Brines from Searles Lake are treated in this modern plant to produce muriate of potash, borax, soda ash, and salt cake. Although other chemical plants are extracting various salts from brines in California, this company is the only producer of potash in the State.

Maryland.—Potash as a byproduct of cement manufacture was recovered from cement-kiln dust by the North American Cement Corporation at its Hagerstown plant. This is the only cement plant in the United States now recovering potash, although during the World War, when potash commanded fabulous prices and was sought from every conceivable source, a number of plants processed the flue dust to extract the potash. The raw material fed to cement kilns may contain 1 percent or more potash.

At Baltimore, potash was recovered from molasses waste at the alcohol plant of the United States Industrial Chemical Co.

New Mexico.—Nearly 600,000 tons of potash ore were mined during 1936 by the two companies operating in the Carlsbad district. Equipment of the mines is ample to handle at least double the tonnage now hoisted. Mechanical equipment underground includes undercutters, electric auger drills, mechanical loaders, electric haulage, and automatic skip loaders. The ore is a mechanical mixture of sylvite (KCl) and halite (NaCl), with insignificant amounts of other impurities.

The refinery of the United States Potash Co. is of the conventional type in which the salts are separated by solution and fractional crystallization, yielding a product of white granular muriate of potash that is better than 99 percent KCl. Operating improvements have stepped up the output of this plant to around 500 tons of muriate a day, about 25 percent above its rated capacity. Increased warehouse facilities add flexibility of operation.

In November the Potash Co. of America completed its No. 2 shaft that will be used primarily for ventilation. The shaft is equipped with a reversible fan of 150,000 c. f. m. capacity that will be operated normally to exhaust air from the mine. At this property, prepara-

¹ Reed, Donald L., and Clark, K. G., Potassium Nitrate from Potassium Chloride and Nitrogen Peroxide: Ind. and Eng. Chem., vol. 29, 1937, p. 333.

tion of high-grade muriate is accomplished by a soap-flotation process in which halite (NaCl) is floated and sylvite (KCl) depressed. The sylvite concentrate, although 96 to 99 percent pure, retains the characteristic red color of the ore. Operation of this plant started in October 1935. It is now being enlarged to double its capacity and is expected to be ready late in 1937 to turn out 400 tons of muriate a day.

The Union Potash & Chemical Co. was formed in January 1936 to consolidate the interests of the Texas Potash Co., the Independent Potash & Chemical Co., the New Mexico Potash Co., and the Carlsbad Potash Co., in a number of prospecting permits that had been explored by drilling. The permits have now expired by limitation, but the company has filed application for three leases of 2,560 acres each covering areas shown by the core tests to contain commercial beds of potash salts. Although the leases had not received the formal approval of the Secretary of the Interior by the early part of 1937, permission was given to continue operations, and a shaft was started in September 1936 at a point about 6 miles directly south of the United States Potash Co. mine. Work was soon stopped but was resumed in February 1937 and in May the shaft was reported to have reached a depth of 218 feet, of which 213 feet had been concreted. Water was encountered at this point, and preparations for sealing it off from the shaft were under way. Core tests indicate a bed of good-grade ore of minable thickness at a depth of about 900 feet. Unlike the other mines in the district, the ore is expected to be a mixture of langbeinite and sylvite, and plans of the company are said include the manufacture of sulphate. It is understood the International Agricultural Corporation, 61 Broadway, New York, has acquired an interest in the property in return for financing development.

All prospecting permits have now expired by limitation, and no new permits or leases were granted during the year.

The New Mexico business privilege tax limited to 1 year enacted in 1934 was reenacted as permanent legislation in 1935 (Chap. 73, Laws of 1935). This law imposes on potash producers a tax of 2 percent on the gross receipts of crude potash sold and $\frac{1}{2}$ of 1 percent on the gross receipts of refined products sold. In addition, the severance-tax law enacted in the spring of 1937 levies a tax of 1 percent on the value of all potash products "computed as of the time when and the place where the same have been severed or taken from the soil immediately after such severance." Both taxes are assessed on gross value after deducting royalties or rentals paid the United States of America or the State of New Mexico.

Utah.—According to a recent announcement, Western Mineral Products, Inc., San Fernando, Calif., will utilize the plant of the Soil-Tone Fertilizer Co. to manufacture fertilizer products from Marysvale (Utah) alunite. The alunite will be calcined, ground, and bagged at the San Fernando plant.

FOREIGN TRADE ²

Imports.—Imports of potash materials for consumption in the United States decreased 109,844 short tons (18 percent) to 493,711 tons. In terms of K₂O, the decrease was only 12 percent, reflecting

² Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

the larger proportion of high-grade salts. The average grade was 43 percent equivalent to 211,766 tons of K_2O compared with an average of 40 percent in 1935. Fertilizer salts comprised 93 percent of the total potash imported, 7 percent being destined for chemical and other industrial uses.

The quantity, average grade, and total declared value of the various potash salts imported in 1935 and 1936, classified by uses, and the approximate K_2O equivalent of imports for the past 5 years are shown in the following tables:

Potash materials imported for consumption in the United States, 1935-36

² Nitrate from Chile calculated at 14 percent K_2O , other countries 40 percent.

Exports.—Exports of fertilizer salts again registered a notable increase. However, this was due entirely to speculative resales and does not represent enlarged export business of domestic producers. In fact fertilizer exports from primary sources decreased from 68,922 short tons of salts equivalent to 41,283 tons of K_2O in 1935 to 61,557 tons equivalent to 37,235 tons of K_2O in 1936. Of recorded exports 41,474 tons containing approximately 24,844 tons of K_2O were drawn from stocks that were doubtless bought for speculative purposes at the attractive low prices prevailing from May 1934 to July 1935 and profitably disposed of at the higher price levels of 1936. The stabilized market of 1936 offered little inducement for speculative buying, and there is no evidence of significant transactions of that nature. Japan and Canada continue to be our best customers for domestic products, although exports to Belgium exceeded those to Canada in 1936. It is obvious that exports of potash fertilizer salts to many of the countries listed in the following table would be improbable, except under extraordinary circumstances.

The chemical salts exported include cream of tartar, potassium bromide, potassium chlorate, potassium citrate, potassium iodide, and saltpeter. Quantities are small, but per-ton values are high.

WORLD PRODUCTION

There are so many gaps in official figures for production in 1936 that only an approximation of world output is possible. In the following table showing metric tons of K_2O in marketable salts produced, 1936 output of Soviet Russia, Spain, and Palestine are estimated. An increase of about 5 percent in the world total is indicated.

¹ In addition to countries listed Chile and Iran are reported to produce a small quantity of potash salts, but statistics of production are not available.² Exports.³ Data not available.⁴ Extracted from waters of the Red Sea.⁵ Content of merchantable products.⁶ Includes some natural kieserite.⁷ Estimated production (Imperial Institute, London).⁸ Extracted from waters of the Dead Sea.⁹ Produced at Solikamsk potash mines.

FOREIGN DEVELOPMENTS

The following comments on the potash industry in foreign countries are based on information drawn largely from official reports to the Bureau of Mines and the Bureau of Foreign and Domestic Commerce. Acknowledgment is made to the following consular officers and commercial agents: Commercial Attaché Gardner Richardson, Vienna, Austria; Assistant Trade Commissioner Wilson C. Flake, Sydney, Australia; Assistant Trade Commissioner Earle C. Taylor, Paris, France; Consul Edwin A. Plitt, Paris, France; Vice Consul R. Austin Acly, Strasbourg, France; Vice Consul Sydney B. Redecker, Frankfort-on-Main, Germany; Consular Clerk W. S. Jesien, Frankfort-on-Main, Germany; Consul David H. Guffum, Leipzig, Germany; Consul General G. K. Donald, Milan, Italy; Trade Commissioner Paul P. Steintorf, Tokyo, Japan; Assistant Trade Commissioner Carl H. Boehringer, Tokyo, Japan; Vice Consul James Espy, Mexico City, Mexico; Consul General Leland B. Morris, Jerusalem, Palestine; Consul General George Wadsworth, Jerusalem, Palestine; Commercial Attaché George R. Cauty, Warsaw, Poland; Consular Clerk M. Pfeiffer, Warsaw, Poland; Vice Consul Charles Will Wright, Warsaw, Poland; Consul Thomas H. Bevan, Warsaw, Poland; Consul Daniel M. Braddock, Barcelona, Spain; Consul Lynn W. Franklin, Barcelona, Spain; Consul E. B. Bower, Stockholm, Sweden.

Australia.—Better prices for wool and wheat resulted in increased fertilizer consumption in 1936 and further expansion of fertilizer sales is anticipated in 1937. During the 1935–36 fertilizer year Australia imported 3,012 tons of potassium sulphate and 7,436 tons of potassium chloride, of which Palestine supplied 700 tons of sulphate and 2,201 tons of chloride.

Austria.—Experimental borings for potash are being carried on at the Hallein mine in Upper Austria. Recent developments are said to offer some encouragement that potash deposits will be found not very far beneath the Hallein salt beds, although the National Geological Association is of the opinion that there are no deposits worth exploiting below the salt beds. If deposits are discovered they could be opened by almost horizontal adits from the valleys.

France.—Total output of 2,099,400 metric tons of potash salts equivalent to 365,200 tons of K_2O in 1936 surpassed by a narrow margin the corrected 1935 figures of 2,027,200 tons of salts and 347,300 tons of K_2O . About two-thirds was supplied by the State mines and one-third by Kali Sainte-Thérèse. Sales totaled 386,000 tons of K_2O , an increase of 40,000 tons from the previous year, but still 106,000 tons behind the record year 1929. In terms of equivalent K_2O , the domestic market absorbed 220,000 tons in 1936 against 155,000 tons in 1935 and 230,000 tons in 1929. Exports dropped 26,000 tons to 166,000 tons. Potash available for export, after supplying the domestic market that must be given priority, was less than the French export quota. The deficiency was made up by other members of the International Cartel. Domestic prices were unchanged in the face of higher costs imposed by labor legislation, but export sales were more profitable following devaluation of the franc. On the whole, the industry enjoyed a prosperous year. Kali Sainte-Thérèse, capitalized at 80,000,000 francs, reported that net profits in 1936 increased 6.8 million to 23,900,000 francs and declared a dividend of 32 percent compared with 22 percent in 1935. The State-

controlled mines likewise have proved very profitable and in the past 12 years have paid 263,000,000 francs in dividends into the State treasury. These mines were acquired by the French Government in 1924 after having been sequestered since 1919. A law regulating their operation that has been before the National Assembly for a number of years finally passed the Senate and was published January 26, 1937. This law provides that the French Government shall remain owner and exploiter of the mines, the profits to be divided between the public Treasury, the three Departments of the Haut-Rhin, the Bas-Rhin, and the Moselle, the former French or allied shareholders whose bonds have not been liquidated, and the agricultural syndicate. The management of these mines is subject to the control of the ministers of Public Works, Agriculture, Commerce, Labor, and Colonies, as well as the Finance Inspection services and the Accounts and Finance Commissions of the Assembly. The law stipulates that all exploiters of potash mines in France, Algeria, and the French colonies shall belong to one common sales agency which will have exclusive sale of their product at prices controlled by the Government. The maximum prices for potash in France and Algeria will be fixed by the Minister of Public Works, in agreement with the Minister of Agriculture for farm use and with the Minister of Commerce for industrial uses. In the French Colonies these maximum prices will be fixed by the Minister of Public Works in agreement with the Minister for the Colonies. The law also provides that in future all new potash deposits in France, Algeria, and the French Colonies shall be reserved for the State.

A decree, effective November 1, 1936, extended to workers in underground potash mines the provisions of the decree of September 25, 1936, limiting working hours in underground coal mines to 38 hours, 40 minutes per week, or 7 hours 45 minutes per day, 5 days a week. Reduction in the hours of labor, increased wages, and paid vacations are expected to result in an increase in the price of potash. However, the workers were not satisfied with these concessions; the trade unions in Alsace immediately demanded a 30-hour week and a stay-in strike broke out in two mines. In February 1937, 10,000 workers in the State mines went out on strike.

A new discovery of seeming importance in the neighborhood of Hettenschlag, Department of the Haut-Rhin, Alsace, was reported during the year. Two bore holes encountered potash at depths of 748 meters and 912 meters, respectively. In the first hole three beds totaled 4.42 meters in thickness and averaged 18.8 percent K_2O . In the second hole also, three beds were found totaling 3.40 meters in thickness and 18 percent K_2O content. The deposit is now estimated to contain about 16,000,000 tons.

A company with a capital of 16 million francs has been formed in Paris to prospect and exploit the potash deposits in the Landes district of southwestern France, formerly held by the Société Minière du Sud-Ouest. It is understood the Government has authorized the State mines to acquire a substantial share in the new enterprise. It is estimated that at least 5 years will be required to develop and equip these properties, by which time it is hoped that consumption of potash will have increased enough to absorb the output of these new mines without disturbing the stability of the domestic market.

Germany.—Consul Sydney B. Redecker, Frankfort-on-Main, reports continued improvement in the German potash industry, though

at a slower pace. The rapid recovery in potash output from the depression low of 1932 slackened in 1936 to an increase of only 39,000 tons of potash in marketable salts, about 3½ percent above the 1935 figure. Although domestic sales expanded around 10 percent, exports fell 1½ percent in bulk and nearly 4 percent in contained K₂O. Notwithstanding this shrinkage in volume, the value of export shipments increased about 16 percent, reflecting higher international prices. A considerable, but undetermined part of 1936 German potash exports was for the account of Spanish producers whose operations were interrupted by the war in Spain. If these shipments later are to be supplied by the Spanish companies the share of 1936 world potash trade for German account was less than German export figures indicate. From the following table of output and sales the notable gains of the past 5 years are apparent. Figures for sales in 1936 are not available but probably approximate those for output used in the table.

Production and sales of potash salts in Germany, 1932-36

Year	Production (thousands of metric tons)				Sales (metric tons K ₂ O)				
	Salts mined		Marketable salts produced		Domestic		Foreign		Total quantity
	Gross weight	K ₂ O	Gross weight	K ₂ O	Quantity	Percent of total	Quantity	Percent of total	
1932.....	6,416	871	12,659	787	641,179	75.7	205,821	24.3	847,000
1933.....	7,363	1,026	3,061	906	716,868	76.4	221,132	23.6	938,000
1934.....	9,617	1,329	4,173	1,179	858,880	70.4	361,120	29.6	1,220,000
1935.....	11,673	1,599	4,716	1,396	920,000	69.2	410,000	30.8	1,330,000
1936.....	11,900	1,644	4,848	1,435	1,040,000	72.5	395,000	27.5	1,435,000

¹ Estimated.

² Production available for domestic consumption.

³ Total production of K₂O in marketable salts.

There was little change in the official domestic schedule of potash prices which, in 1935, resulted in average prices, delivered at any railroad station in Germany, ranging from 17 marks per metric ton for raw salts (12 to 15 percent K₂O) to 84.8 marks for 50 percent muriate and 113 marks for sulphate. On the other hand, the average export value of raw salts jumped from 29.62 marks per metric ton in 1935 to 38.36 in 1936 and that of processed potash from 57.91 marks in 1935 to 66.42 in 1936. The rise in net profits of the four leading potash companies, controlling four-fifths of the industry, from a total of 9.9 million marks in 1934 to 11.1 million in 1935 is believed to have continued in lesser degree in 1936. A recent decree established a price reduction of 25 percent effective May 16, 1937.

Faced in recent years with growing competition in the foreign potash trade, German potash companies have sought by technical improvements to reduce production costs; markets for byproduct materials (magnesium and sodium salts, borax, and bromine) have been developed further; new interests in the nitrogen and crude petroleum industries have been acquired; and during 1936 large plants have been constructed to manufacture synthetic gasoline and magnesium-metal alloys. Carnallite, a low-grade potash salt abundantly available in existing mines, supplies the raw material from which magnesium metal is extracted by processes recently perfected. These industries, under-

taken by the larger companies (notably Wintershall A. G., leading world potash producer with 50-percent control of the German potash industry) as adjuncts to their basic potash business, have received great impetus from Germany's struggle to attain national self-sufficiency.

New legislation extended for 3 years the law granting sellers of fertilizer prior liens upon farmers' crops. This has already been in effect 3 years and has resulted in expanding the national consumption of fertilizers. The Government also renewed for a further year the system of export-subsidization instituted in 1935, whereby manufacturers are required to pay a special tax, ranging from 2 to 9 percent of their domestic turn-over, for supplying a national fund from which subsidies are granted exporters to enable them effectively to meet foreign competition. Financial progress of the industry is being retarded by the steadily rising burden of taxation to support the Government's aggressive economic nationalism, rearmament, and public-works programs. A 50-percent increase in corporate income tax was decreed in the latter part of the year, raising the tax from 20 to 30 percent of the total net profits realized. Profits disbursed to shareholders were depressed by compulsory payment into Government loans of all dividends above 8 percent of the nominal stock value and all dividend increases above 6 percent. It is estimated that German companies will pay in taxes 50 to 60 percent of their net profits. The potash industry, drawing its supplies from abundant domestic sources, is little concerned with Government decrees restricting and guiding consumption of raw materials that hamper industries normally dependent on imports or limited domestic resources.

Italy.—Annual production of potassium salts from molasses residues at the plant put in operation in 1935 by L'Appula Soc. Anon. is now reported to be 4,000 tons. The salts produced include chloride, sulphate, bicarbonate, hydroxide, and metabisulphite. It is alleged that a large deposit of potash salts has been discovered near Calascibetta, Enna Province, Sicily. Italy now depends upon foreign countries for its potash requirements. Efforts to produce commercial supplies of soluble potash and aluminum from leucite deposits have been abandoned as uneconomic.

Japan.—Growing demand for potash fertilizers has stimulated efforts to recover potash from various domestic sources. Residual brines from evaporation of sea water to produce salt contain substantial amounts of potash. A professor at the Tokyo Imperial University is reported to have patented a process of treating residual brines with aluminum sulphate to yield potassium sulphate, the aluminum sulphate being recovered for further use. It is estimated that approximately 18,000 metric tons could be recovered annually from residual brines of the salt industry. Two processes are said to have been developed for treatment of molasses at alcohol distilleries to produce potash salts. One process is alleged to recover 95 percent of the potash content of molasses by treatment with aluminum sulphate, the yield of alcohol being unaffected. The production of potash chemical salts likewise is receiving increased attention. Potassium ferrocyanide and potassium permanganate are now being produced by the Mano Chemical Works at the rate of 5 and 10 tons, respectively, per month. Japanese producers of potassium chlorate reached an agreement on March 30, 1937 with the European potassium chlorate syndicate with respect to sales territories and export quotas

for the year 1937. Japan is allocated a total of 6,900 metric tons for the year, representing the entire consumption of Japan and Manchuria, 55 percent of that of China, and a small percentage of other markets.

Mexico.—Discovery of a large deposit of alunite in the State of Guanajuato is reported. The deposit, said to occupy an entire hill 15 miles west of Comonfort, is estimated by the Instituto de Geologia to contain 2,943,000 tons in sight. The deposit is said to be 40 percent pure alunite and to contain 18.45 percent alumina and 4.57 percent combined potash and soda.

Nigeria.—Exports of potash have approximated 100 long tons annually for the past 5 years. Potash is also said to be an important item in internative trade.

Palestine.—Exports of potash from Palestine increased in 1936 to 23,372 metric tons valued at £132,857 from 18,124 tons valued at £80,231 in 1935. The Palestine Potash, Ltd., concessionaire for extraction of potash and other chemicals from the waters of the Dead Sea, reported production and sales increased in 1936 and prices improved following the conclusion early in the year of agreements with European producers. The political disturbances in Palestine during the year did not affect operations and sales but caused some transport difficulties. Jewish and Arab employees of Palestine Potash, Ltd., worked peaceably side by side throughout the disturbances. Work proceeded on the new plant at the southern end of the Dead Sea that is expected to be ready for operation in 1937. About one-fourth of the area of evaporating pans at the north end of the Dead Sea is in Trans-Jordan.

It is believed that the International Potash Cartel pact with Palestine relates particularly to distribution to the newer markets in Near Eastern and Far Eastern countries that are expected to develop rapidly as the result of the educational and sales propaganda work of the cartel. The Palestine industry is particularly well situated to reach these markets, and it is reported that construction of a cable railway from the Dead Sea to the ocean harbor will reduce f. o. b. ocean-port costs to around 40 percent below those of the German industry.

Poland.—Production of crude salts increased 49,000 metric tons to 434,000 tons, equivalent to 85,000 tons of K_2O , in 1936. This is an all-time high and indicates growing domestic use, since exports, controlled by Poland's quota in the International Potash Cartel, remained virtually stationary at 83,000 tons of merchantable salts. The industry is practically a Government monopoly, the mines being owned by the Government and the sales organization controlled by it through the National Economic Bank. The domestic market is protected by an import duty of 16.50 zlotys (\$3.13) per ton. Reserves were estimated in 1935 by the Polish Geological Survey at 450 million tons.

Spain.—Notwithstanding continuance for some months of low prices nominally terminated in April 1935 by agreement with the International Cartel, Spanish producers enjoyed a profitable business in 1935 and faced 1936 with prospects of continued improvement under stabilized market conditions. However, the outbreak of civil war following the revolt of the army closed the mines in the late summer, and about September the directors of the three companies were obliged to flee the country. The mines had continued to operate and

accumulate stocks at Barcelona for some time after shipments were no longer possible because of the high premiums demanded for insurance. The last shipment of potash from Spain to enter the United States was 1,966 tons of chloride imported in July. The mines are in Catalonia in an area controlled by the Government and are said to have been kept in good condition, under the management of control committees set up by the workers. They are reported to be subject to a new Catalan decree of collectivization for the appropriation of large enterprises. However, it is stated that, in view of the foreign capital in these three companies, the Catalan minister will only settle the question of appropriation after discussion with the owners. In October it was learned that potash was being shipped from Barcelona, and on December 15 the steamer *Beatsa* arrived at London with a cargo believed to be Spanish potash. An injunction was obtained on behalf of the three Spanish companies owning all the potash mines in Spain to prevent delivery of the cargo to the consignees on the ground that it belonged to the mine owners. The court will have to decide whether the mines have been validly sequestered by the Spanish Government. More recently it has been reported that the Spanish Government, badly in need of exports to balance the large import of war materials, will take special measures (presumably price concessions) to foster the export of potash, large stocks of which have accumulated. The mines were reported in December to have resumed operations, and it is said that a project has been drawn up for socializing them and that the product may be dumped abroad at cut prices. In that event, it is conceivable that world markets again may be demoralized by Spanish potash. As yet world trade has not been affected by cessation of shipments from the Spanish mines, as the Spanish quota has been supplied by other members of the International Potash Cartel.

Sweden.—According to a Government survey, potash salts could be produced in southern Sweden in sufficient quantity to supply at least half of the domestic demand.

U. S. S. R. (Russia).—No figures for output of potash in the U. S. S. R. in 1936 are yet available. However, production of the Solikamsk mines is now well-established, having reached 1,319,000 tons in 1935, and it is conceivable that the 1936 quota of 1,800,000 tons may have been approximated. The mine is said to be thoroughly mechanized throughout with modern equipment, but to reach the goal of 3,000,000 tons set for 1937 will require further extension of workings. Labor productivity has shown steady improvement as the workers become more familiar with their tasks. A second mine being equipped near Berezniki is expected to start production before the end of 1937. Soviet officials are fully alive to the benefits of fertilization, and the Commissariat for Agriculture has recommended the use of 1,600,000 metric tons of potash salts a year. The present output of finished salts is around 400,000 tons annually, so it appears that domestic requirements may be expected to absorb expanding output for some years to come. Except for nearby eastern European countries, little Russian potash has appeared in world markets since 1934. Another discovery was reported recently in West Kazakhstan, near the Volga River. The deposits are said to be high in potash content and close to transportation. They are favorably located for supplying the southern part of the country, which suffers seriously from lack of fertilizers.

MICA

By BERTRAND L. JOHNSON and M. A. CORNTHWAITE

Domestic sheet mica.....	1405	Exports.....	1410
		World production.....	1411

As a result of increased demand for both uncut sheet mica and scrap mica, the quantity and value of domestic mica sold or used by producers in the United States in 1936 increased over 1935. Sales of scrap mica decreased in North Carolina and New Hampshire but increased in Connecticut. Sales of uncut sheet mica in 1936 were lower in Connecticut but higher in North Carolina and New Hampshire than in 1935.

Total scrap-mica sales, including fine mica obtained in washing kaolin and grinding micaceous schists, increased 2,103 short tons, over 1935, due largely to an advance in the production of byproduct mica and mica from schists, as the production of true scrap rose only 512 tons over 1935. Sales of true scrap in 1936 were 12,697 tons compared with 12,185 tons in 1935. In contrast, sales of mica obtained from washing kaolin and grinding schists increased from 6,667 tons in 1935 to 8,258 in 1936.

Prices of domestic sheet mica rose toward the end of the year. As in 1935, prices of imported sheet mica were higher than those of similar domestic mica. Prices of India splittings showed fractional rises during 1936, and prices of Madagascar splittings were steady throughout the year.

Both the quantity and value of imports of mica in 1936 increased markedly over 1935. Imports of splittings in 1936 were nearly a million and a half pounds greater than in 1935. Exports of mica and mica products in 1936 were slightly less in quantity but somewhat higher in value than in 1935.

The following table summarizes the principal statistics of the mica industry in the United States from 1933 to 1936.

Figure 115 shows the quantity and value of mica splittings and of the better grades of sheet mica imported into the United States since 1926, also the domestic production of sheet mica in sizes larger than punch during the same period.

FIGURE 115.—Trends in imports of splittings, and of imports and domestic production of the better grades of sheet mica, 1927-36.

¹ Includes mica recovered from kaolin and schists as follows: 1935: 6,667 tons valued at \$111,345; 1936: 8,258 tons valued at \$127,343.

² Includes fine unground mica recovered in washing kaolin and, in 1935 and 1936, mica recovered by milling mica schist.

³ Includes a small quantity of scrap imported for grinding.

⁴ Exclusive of a nominal quantity of splittings produced in South America and the United States.

PRODUCTION

Sheet and scrap.—The quantity and value of the domestic production of both sheet and scrap mica increased in 1936 over those in 1935. The domestic production came principally from three States—Connecticut, New Hampshire, and North Carolina. Other producing States were Alabama, Arizona, Colorado, Georgia, Maine, New Mexico, South Carolina, South Dakota, and Virginia. The quantity and value of scrap mica produced in New Hampshire and North Carolina decreased and increased in Connecticut. Production of uncut sheet mica in Connecticut in 1936 was below the level of 1935, but the value of the production increased. Increases were reported in both the quantity and the value of production from New Hampshire and North Carolina. The following tables show the quantity and value of the various classes of domestic mica sold or used by producers in the United States and in the producing States of New Hampshire and North Carolina for 1932 to 1936 and Connecticut for 1935 and 1936. From 1932 to 1934 there were too few producers of mica in Connecticut to permit publication of the figure for the sales of mica.

Domestic mica sold or¹ used² by producers³ in the United States, 1932-36

Year	Sheet mica						Scrap mica		Total

¹ Bureau of Mines not at liberty to publish figures for earlier years.

² Includes mica recovered from kaolin and schists as follows—1935: 4,299 tons valued at \$75,659; 1936: 5,265 tons valued at \$82,903.

Ground mica.—The quantity of ground mica sold by domestic producers in 1936 was 23,418 short tons valued at \$674,807, compared with 18,323 tons valued at \$542,973 in 1935. The 1935 and 1936 figures given in the tables for ground mica and scrap mica include ground muscovite, sericite, and chlorite schists, therefore they are not comparable with those for earlier years which did not include the production from schists.

The following companies, classified according to their method of grinding, reported production of ground mica to the Bureau of Mines in 1936:

	<i>Process</i>
Asheville Mica Co., Biltmore, N. C.....	Dry.
Concord Mica Co., Concord, N. H.....	Wet.
Franklin Mineral Products Co., Franklin, N. C.....	Do.
General Mica Co., Inc., Pueblo, Colo.....	Dry.
Newdale Mica Co., Irwin, Tenn.....	Do.
Richmond Mica Corporation, 323 South 9th St., Richmond, Va.....	Wet.
Southern Mica Co., Johnson City, Tenn.....	Dry.
Southern Mining & Milling Co., Clarksville, Ga.....	Wet.
Standard Oil Co., 910 South Michigan Ave., Chicago, Ill.....	Dry.
U. S. Mica Manufacturing Co., 1521-1527 Circle Ave., Forest Park, Ill.....	Do.
D. T. Vance, Plumbtree, N. C.....	Wet.
Vance-Barrett, Inc., Plumbtree, N. C.....	Do.

The following tables show the quantity and value of wet-ground and dry-ground mica sold by producers in the United States from 1932 to 1936 and sales by uses in 1936. Sales of ground mica for use in paint, which are shown for the first time for 1936, represented 6 percent of the total sales and ranked third among the uses of ground mica. The figures for dry-ground mica include sales of byproduct mica recovered by the Harris Clay Co. and the General Mica Co. in washing kaolin in Mitchell County, N. C., and for 1935 and 1936 the product obtained by grinding muscovite, sericite, and chlorite schists. Sales of this latter material in 1936 were reported by L. E. Shepard, Buckeye, Ariz.; Thompson Weinman & Co., Inc., Cartersville, Ga.; and Victor Mica Co., Spruce Pine, N. C.

Ground mica sold by producers in the United States, 1932-36, by methods of grinding

	Short tons	Percent of total	
Roofing ²	18,112	77	\$384,884
Wall paper.....	2,869	12	166,315
Paint.....	1,307	6	71,155
Rubber.....	516	2	27,012
Miscellaneous ³	614	3	25,441
	23,418	100	674,807

¹ Includes a small quantity of scrap imported for grinding.

² Includes ground mica from schist.

³ Figures cover mica used for molded electric insulation, surfacing on asphalt shingles, Christmas-tree snow, manufacture of axle greases and oil, annealing, concrete and foundry facing, pipe-line enamel, plastic specialties, and other purposes.

Figure 116 shows trends in the percentage of ground mica used in various industries from 1927 through 1936. During this period the roofing industry has become the major outlet and the wallpaper and rubber industries, which formerly were important users, now use relatively little.

FIGURE 116.—Percentage of ground mica used by consuming industries in the United States, 1927-36.

CONSUMPTION AND STOCKS OF MICA SPLITTINGS

The consumption of mica splittings, a raw material of major importance in the domestic mica-products industry, exceeded 3,500,000 pounds in 1936, a marked increase over 1935. Virtually the entire supply was imported, as the domestic mica industry yields only a few thousand pounds of these thin flakes annually. Nearly 90 percent came from India, the world's largest producer of mica splittings, which furnished to United States consumers over 901,000 pounds more than in 1935. Domestic consumption of mica from Madagascar likewise increased over 1935, but that of mica from Canada declined.

Stocks of mica splittings in the hands of consumers on December 31, 1936, were slightly greater than at the end of 1935. Stocks of Indian and Madagascan splittings were larger than in 1935 and more than counterbalanced the decline in stocks of Canadian mica splittings.

The accompanying tables show the quantity, value, and source of mica splittings consumed in the United States from 1932 to 1936 and stocks in the hands of consumers on December 31, 1935 and 1936.

*Mica splittings consumed in the United States, 1932-36, by sources, as reported by the consumers*¹

Domestic sheet mica.—Demand for sheet mica for electrical purposes was strong throughout the year, and as domestic production was inadequate to supply the demand considerable quantities were imported from India, Brazil, and Argentina. Prices of domestic mica rose toward the end of the year, carrying the 1936 average above that of 1935. The accompanying table shows the range in prices of domestic uncut mica f. o. b. North Carolina, as reported in Metal and Mineral Markets. These prices apply both to No. 1 and No. 2 clear; stained mica is 10 to 25 percent less than the prices given. The form of table is slightly different from that used in previous years to show the increases in prices of the larger grades that occurred at intervals in 1936.

Size	Price per pound	Size	Price per pound
Punch-----	\$0.03-\$0.05	3 by 4 inches: Jan. 1-Apr. 18-----	\$0.90-\$1.25
½ by 2 inches-----	.15-.30	Apr. 19-Dec. 31-----	1.00-1.25
2 by 2 inches-----	.30-.50	3 by 5 inches-----	1.25-1.50
2 by 3 inches: Jan. 1-May 16-----	.50-.65	4 by 6 inches: Jan. 1-Apr. 18-----	1.50-2.50
May 17-Dec. 31-----	()	Apr. 19-Dec. 31-----	2.00-2.50
3 by 3 inches: Jan. 1-Apr. 18-----	.65-.85	6 by 8 inches-----	2.50-3.50
Apr. 19-May 16-----	.75-1.00	8 by 10 inches: Jan. 1-May 16-----	4.00-5.00
May 17-Dec. 31-----	.75-1.10	May 17-Dec. 31-----	3.50-5.00

Foreign sheet mica.—Considerable stained sheet mica for electrical purposes was imported to supplement domestic supplies in 1936, and, as in 1935, the prices of this imported mica were higher than those of similar domestic mica. Except for some cheaper stained material from Madras, Brazil, and Argentina, most of the sheet mica imported was large, clear mica for special purposes; No. 6 "good-stained" mica for tube supports; and Nos. 5, 5½, and 6 grades of split condenser mica. London prices for sheet mica of electrical quality rose moderately during the year, but the outstanding feature of the market was the sharp increase in the prices of all grades of superfine clear and slightly stained mica of any origin and of special and better grades of good sheet. During the year all stocks of clear and slightly stained mica are reported to have been exhausted, and the supply was insufficient for the demand. Prices for mica of this quality at the end of the year were well above the average for the year. In general, the market for all classes of sheet mica on January 1, 1937, was firm, with an upward tendency.

There are no definite New York quotations for foreign mica, but the following table, based on actual sales during the year, gives a close approximation of New York prices.

Approximate average prices per pound of uncut sheet mica in New York in 1936

Domestic			India (duty paid) ¹

¹ Prices of India mica calculated on basis of £1 equals \$4.80.

Splittings.—While the prices of India splittings in 1936 showed only fractional rises, consumption increased rapidly in November and December and continued heavy in the first quarter of 1937. In fact, during the first quarter of 1937 the quantity of India splittings used in the United States was more than double that used in the corresponding months of 1936. The increased consumption was reflected by heavy buying which commenced in January 1937. This heavy buying and increased demand in Europe absorbed all available stocks in India and London and caused sharp rises in the prices of all grades of India splittings, which in May 1937 were selling at 50 to 75 percent above the 1936 averages.

Average prices for India splittings, ruby muscovite, duty paid, in New York in 1936 were as follows: No. 4, book-packed, \$1.20; loose \$0.75; No. 5, book-packed, \$0.80; loose \$0.53; No. 5½, book-packed, \$0.75; loose, \$0.30; No. 6, book-packed, \$0.55; No. 6, first-quality, loose, \$0.23; No. 6, second-quality, loose, \$0.175; No. 6, third-quality, loose, \$0.13; cheap, loose, \$0.10.

Consumption of Madagascar splittings early in 1937 was also more than double that of a year earlier. Prices, however, remained steady, probably being influenced by the devaluation of the French franc. Average prices in 1936 for Madagascar splittings, phlogopite, duty paid, New York, were as follows: No. 4, loose, 65 cents a pound; No. 5, loose, 50 cents a pound; and No. 6, loose, 43 cents a pound.

Scrap.—The average price of domestic scrap mica f. o. b. mill in 1936 was \$12.44 a ton; in 1935, it was \$12.94.

Ground mica.—The average price of dry-ground mica f. o. b. mill in 1936 was \$21.97 compared with \$22.52 a ton in 1935. Wet-ground mica sold at an average price of \$55.46 a ton in 1936 compared with \$63.96 a ton in 1935.

FOREIGN TRADE¹

Imports.—Imports of mica in 1936 totaled 13,355,587 pounds valued at \$1,205,568 compared with 9,756,493 pounds valued at \$908,384 in 1935. Imports of unmanufactured mica (8,646,446 pounds valued at \$262,044) and imports of manufactured mica (4,709,141 pounds valued at \$943,524) also increased in quantity and value over 1935. Imports of splittings in 1936 exceeded those in 1935 by 1,425,880 pounds. The accompanying table shows the classification, quantity, and value of mica imported for consumption in the United States in 1936 and the countries from which it was last shipped.

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Exports.—Exports of mica and manufactures thereof in 1936 (2,955,040 pounds valued at \$170,011) were slightly less in quantity but a little greater in value than those in 1935 (2,998,762 pounds valued at \$165,385). Exports of unmanufactured mica in 1936 amounted to 367,672 pounds valued at \$6,671, and those of manufactures of mica 2,587,368 pounds valued at \$163,340. The accompanying table shows the quantity, value, and destination of mica and mica products exported from the United States in 1936.

SALT

Salt produced for sale or use by operators of salt mines, wells, and ponds in the United States in 1936 totaled 8,828,936 short tons, 11 percent more than in 1935, 3 percent more than the former peak production of 8,543,560 tons in 1929, and 38 percent more than the low level of 6,407,973 tons in 1932. The output was valued at \$23,306,177 compared with \$21,837,911 in 1935, an increase of 7 percent. The average value in 1936 was \$2.64 a ton, 11 cents less than in 1935. The output of all classes of salt increased in 1936. The total output of dry salt sold (rock and evaporated) increased 11 percent, and the salt content of the brine used in the manufacture of chemicals increased 12 percent.

Seventy-two plants (58 companies) reported operation in 1936 compared with 74 plants (60 companies) in 1935.

Of the 58 companies reporting operation in 1936, 7 large companies, including producers of evaporated salt, rock salt, and brine, produced about 47 percent of the total. In addition, 16 medium-size companies produced about 44 percent, and the remaining 36 small companies produced 9 percent.

According to H. I. Smith, of the United States Geological Survey, the salt produced from leases on public domain administered by the United States Government amounted to 7,132.12 short tons valued at \$14,908 in 1936. The royalty on the salt ranged from 2 to 5 percent of the gross value and totaled \$625.37.

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

FIGURE 117.—Index of salt sold or used compared with Federal Reserve Board index of industrial activity, 1919-36.

If the average annual salt production for 1923-25 is taken as 100 and compared with the Federal Reserve Board index of general business, the accompanying graph (fig. 117) reveals that the production of all kinds of salt followed the index of general industrial activity closely for a number of years. Salt production remained relatively high during the depression—at the lowest point in 1932 the index was 26 points above that of general business—and climbed to an all-time high in 1936. The dry-salt curve, which is relatively inflexible because of the large quantity used by the food industries, lagged behind the index of general business from 1925 to 1929 but did not drop so low during the depression years. Although shipments increased in 1936 compared with 1935, the output of dry salt was less than the 1929 peak, and the index fell slightly below that of business in general.

The use of chlorine increased in 1936, particularly in the South where new kraft-paper mills are springing up rapidly, forecasting increased salt production. At least one large company already is reported to have perfected plans for a new chlorine plant in Louisiana.

Imports, which were never large compared with domestic output, remained virtually unchanged in 1936, and exports declined. As in past years, exports exceeded imports by a wide margin. Table salt predominates in the exports and crude salt in the imports. Increased activity in the fishing industry of the Eastern Shore of Virginia has resulted in a steady increase in imports of salt for curing fish, and in 1936 they almost equaled the combined receipts of the two customs districts, Maine and New Hampshire, and Massachusetts.

PRODUCTION

The vast resources of salt in the United States tend to foster overdevelopment, and existing mines commonly are idle part of the year. This situation has led to consolidation of some companies. Usually there are no seasonal changes in the level of the salt business. Local conditions, such as canneries that consume large quantities of salt during their canning season, may affect consumption in some parts of the country, and the rainy season on the west coast influences the production of solar salt, but the variation in a year for the entire country is small.

Minerals Yearbook, 1936 (p. 920), contains a directory showing producing companies, location of plants, and class of salt produced, marketed, or used by them. The following changes and additions to this directory bring it up to date through 1936.

In 1936 the Arden Salt Co. and the Leslie California Salt Co., operating in Alameda County, Calif., were consolidated and now operate as the Leslie Salt Co. (address, 310 Sansome Street, San Francisco, Calif.). The Irvine Salt Co., Tustin, Calif., started operations but made no production. The Michigan Chemical Corporation, producing evaporated salt and bromine, started operations at St. Louis, Mich., and the Great Lakes Chemical Corporation had a plant under construction at Filer City, Mich. At Carlsbad, Eddy County, N. Mex., salt recovered as a part of the process of refining potassium salts at the plant of the Potash Co. of America was marketed by the Salt Supply Co., Carlsbad, N. Mex.

Further interest is attached to the merger of the Leslie-California Salt Co. with the Arden Salt Co., which has interesting and unique methods of harvesting the solar salt, as the Alviso Salt Co., previously taken over by the Arden Salt Co., pioneered in the methods of harvesting solar salt.

By one of the methods employed a Diesel-powered harvester, especially designed for handling crude salt, travels across the pond, picks up the salt that has been deposited on the bottom of the pond, and unloads it in dump cars that run on a portable track alongside. Another method used is to harvest the salt automatically with a tractor-powered machine having an endless belt that picks it up and conveys it to dump cars hauled by a miniature gasoline locomotive. The salt goes in cars to the washer, to an elevator conveyor, and thence to outside storage piles, where it is kept until final shipment is made. The steep sides of the storage piles become caked with a hard crust that is impervious to the rain.

Production by States.—Michigan continued to be the leading salt-producing State, followed by New York, Ohio, Louisiana, and Kansas.

² 1934, Nevada, New Mexico, Oklahoma, Puerto Rico, Utah, and Virginia; 1935, Nevada, New Mexico, Oklahoma, and Virginia; 1936, New Mexico, Oklahoma, and Virginia.

Evaporated salt.—Evaporated salt, produced either from the original brine of wells and ponds or from brine obtained by forcing water into beds of rock salt and withdrawing it for processing, represented 29 percent of the quantity of salt produced in 1936. The output, 2,539,597 short tons valued at \$15,581,148, increased 9 percent in quantity and 5 percent in value over 1935. These figures include salt blocks made from evaporated salt and sold mostly for cattle licks. In 1936 the production of salt blocks from evaporated salt amounted to 134,586 short tons valued at \$965,114, an increase of 7 percent in both quantity and value over 1935. The average value per ton of all evaporated salt was \$6.14, 20 cents less than in 1935. Due to the processing methods applied to this class of salt, the average unit value is higher than that of rock salt.

Michigan retained first place as a producer of evaporated salt, followed by Ohio, New York, California, and Kansas. In 1936, 38 plants reported sales of salt processed by vacuum-pan or grainer systems, 18 sold solar-evaporated salt, and 17 made blocks from evaporated salt.

¹ Includes a quantity of salt content of brine for chemical use reported as evaporated salt with value as evaporated salt.

² Louisiana, New Mexico, Oklahoma, Texas, and Utah.

Rock salt.—The output of rock salt was 2,009,579 short tons valued at \$6,003,054 in 1936 compared with 1,759,242 tons valued at \$5,510,413 in 1935, an increase of 14 percent in quantity and 9 percent in value. The average value of rock salt in 1936 was \$2.99 a ton, 14 cents less than in 1935. The figures for rock salt include pressed blocks made from rock salt which amounted to 34,489 short tons valued at \$222,864 in 1936, an increase of 40 percent in quantity and 43 percent in value over 1935. Nineteen plants reported production of rock salt in 1936, and seven plants produced blocks. In 1936 New York, Louisiana, Kansas, and Michigan produced 93 percent of the rock salt mined. Other States reporting production of rock salt were Texas, California, Utah, and New Mexico. On account of the small number of producers of rock salt and salt in brine for chemical manufacture and of rock salt and evaporated salt in certain States, it is impossible to show either rock salt or salt in brine used for chemicals separately by States, if State totals for all classes of salt are published.

Rock salt sold by producers in the United States, 1932-36

Year	Short tons	Value	Year	Short tons	Value
1932-----	1,584,731	\$5,100,779	1935-----	1,759,242	\$5,510,413
1933-----	1,784,992	5,570,352	1936-----	2,009,579	6,003,054
1934-----	1,913,182	6,306,095			

Salt content of brine.—The quantity of salt in brine sold or used by producers for the manufacture of chemicals in 1936 was 4,279,760 short tons, an increase of 12 percent over 1935. This class of salt represented 48 percent of the total output and was produced at 10 plants—at Cameron and Iberville Parishes, La.; Detroit and Wyandotte, Mich. (2 plants); Barborton and Painesville, Ohio; Tully, N. Y.; Benavides, Tex.; and Saltville, Va.

Pressed blocks.—The production of pressed blocks from both evaporated and rock salt reported by the original producers of the salt and shown in the following table does not represent the entire pressed-block industry, as some firms that do not produce salt make pressed blocks from salt bought in the open market. The total production of blocks in 1936 was 169,075 short tons valued at \$1,187,978, an increase of 12 percent in both quantity and value over 1935. Eighty percent of the blocks were made from evaporated salt, and the output of each class increased in 1936. Pressed blocks from evaporated salt are made chiefly by salt producers in Kansas and Michigan, but are also produced in California, Texas, Utah, Ohio, Louisiana, and New York. Pressed blocks from rock salt are made chiefly by producers in Louisiana and Kansas, and small amounts are made in Texas.

Pressed-salt blocks sold by original producers of the salt in the United States, 1932-36

Year	From evaporated salt		From rock salt		Total

SHIPMENTS

Shipments of evaporated and rock salt in the United States in 1935 and 1936, given in the following table, were compiled from reports of producers. No account was taken of reshipment beyond the original destination indicated when the salt left the producing plant. The figures contain no salt shipped by jobbers, dealers, or producers shipping salt obtained from other producers.

USES

Salt is employed for so large a variety of purposes and marketed so widely throughout the country that satisfactory figures have never been compiled of quantities used annually for even the most common uses. It is possible, however, to show salt production by methods of manufacture, as in the following table, and to quote estimates by uses.

Salt sold or used by producers in the United States, 1935-36, by methods of manufacture

Method of manufacture	1935		1936	
	Short tons	Value	Short tons	Value
Evaporated in open pans or grainers.....	466, 327	\$3, 738, 642	595, 143	\$4, 352, 907
Evaporated in vacuum pans.....	1, 390, 587	8, 835, 410	1, 457, 364	8, 910, 069
Solar evaporated.....	347, 123	1, 298, 859	352, 504	1, 353, 058
Pressed blocks from evaporated salt.....	126, 005	900, 040	134, 586	965, 114
Rock.....	1, 734, 551	5, 354, 411	1, 975, 090	5, 780, 190
Pressed blocks from rock salt.....	24, 691	156, 002	34, 489	222, 864
Salt in brine (sold or used as such).....	3, 837, 613	1, 554, 547	4, 279, 760	1, 721, 975
	7, 926, 897	21, 837, 911	8, 828, 936	23, 306, 177

Salt brine used for chemicals and never reaching the market as dry salt comprised almost half of the total salt produced in 1936, as in the last few years. Of the estimated domestic distribution of chemical raw materials in the process industries, about two and two-thirds times as much salt was used as all other basic materials together.

The following estimate of salt consumption was extracted from a table on domestic distribution of chemical raw materials in the process industries.¹

	Short tons		Short tons
Sugar and food products.....	1, 200, 000	Soap and glycerine....	40, 000
Leather, glue, and gelatines.....	350, 000	Oils, fats, and greases....	5, 000
Dyes and organic chemicals.....	207, 000	Glass and ceramics.....	3, 000
Textile processing.....	40, 000	Other industries.....	1, 405, 000

It is estimated that 85 percent of the total salt produced is used in process industries and 15 percent in other industries.

¹ Chemical and Metallurgical Engineering, Annual Review Number, February 1937, pp. 58-59.

Additional uses have been found for chlorine derived from salt, which formerly was unsalable in the market, and the estimate of its use by industries is as follows:

	Short tons		Short tons
Pulp and paper.....	145, 000	Textile processing.....	11, 000
Dyes and organic chemicals....	80, 000	Total for process industries....	281, 000
Heavy chemicals.....	45, 000	Total for other industries.....	38, 300

Of a total distribution of 319,300 short tons of chlorine 88 percent is used in process industries and 12 percent in other industries.

The trend in consumption of chemical processes that use raw-salt derivatives, based on 1929 as 100, was given for 1930-36 as follows:

*Trends in salt-consuming industries, 1930-36*¹

[1929=100]

	1930	1931	1932	1933	1934	1935	1936

Chlorine.....	92.96	90.95	92.96	107.54	150.76	160.30	180.9

¹ Chemical and Metallurgical Engineering, February 1937, p. 61.

Probably the greatest immediate growth of the salt industry will be expansion of chemical uses. The electrolysis of salt added many new outlets to the already multiple uses. In establishing electrolytic plants cheap electric current and availability of nearby markets are the principal factors to be considered if profitable business is to be developed.

MARKETING

Dry-salt price competition was keen the first part of 1936 but quieted down toward the end of the year. It was not apparent in the scheduled prices, which remained about the same, but special discounts, terms, and concessions said to exist made the actual prices vary widely.

An active subject of contention was the sale of industrial salt in bulk. The salt industry has tried for years to eliminate bulk sales of salt to resellers of the salt, preferring to sell bulk salt direct to consumers in carload lots only and packaged salt to resellers, as they often found themselves in competition with their own salt when jobbers to whom they had sold the salt in bulk packaged and sold it to consumers at lower prices than the producer sold to the consumer. In some sections of the United States no bulk salt is being shipped at present, and it appears that the question has not yet been settled satisfactorily.

FOREIGN TRADE

Exports of salt decreased 31 percent in quantity and 16 percent in value in 1936 compared with 1935. The main decrease was the 60-percent reduction in shipments to Japan, although substantial declines occurred also in shipments to Cuba and Canada. These three countries accounted for 91 percent of the salt exported in 1936 against 94 percent in 1935.

Imports of salt decreased slightly in 1936; smaller shipments from Spain and several less important sources were not quite balanced by larger imports from British West Indies and French Africa.

¹ In addition to the countries listed salt is produced in Bolivia, Gold Coast, Madagascar, and Southern Rhodesia, but figures of production are not available.

² Data not available.

³ Exports.

⁴ Railway shipments.

⁵ Estimated annual production.

⁶ Sales.

⁷ Output of U. S. S. R. in Asia included with U. S. S. R. in Europe.

⁸ Includes Manchuria.

⁹ Salt issued by the Government for sale.

¹⁰ Year ended Mar. 31 of year following that stated. The figures do not include output from salt beds which, although situated on Government beach lands, have no fixed areas.

¹¹ Year ended Mar. 31 of year following that stated.

BROMINE

The figures for bromine production in this report comprise the quantity of bromine recovered by the producers from natural brines and the bromine content of bitters used by producers in the manufacture of bromine compounds. The largest part of the bromine output reported is not sold as bromine but as ethylene dibromide, potassium and sodium bromide, and other bromine compounds. In 1936 the bromine produced amount to 20,609,025 pounds valued at \$4,038,438, an increase of 25 percent in quantity and 16 percent in value over 1935.

Bromine and bromine in compounds sold or used by producers in the United States, 1932-36

Year	Pounds	Value	Year	Pounds	Value
1932.....	5,727,561	\$1,182,569	1935.....	16,428,533	\$3,483,239
1933.....	10,147,960	2,040,352	1936.....	20,609,025	4,038,438
1934.....	15,344,290	3,227,425			

The Ethyl-Dow Chemical Co., which began to extract bromine directly from sea water at Wilmington, N. C., in 1934, is the largest producer of bromine in the United States, and enlargement of the plant in 1936-37 is reported. Other companies that produce bromine are the California Chemical Co. (address, Newark), Chula Vista, Calif.; Michigan Chemical Corporation, St. Louis, Gratiot County, Mich.; Rademaker Chemical Corporation, Eastlake, Manistee County, Mich.; Morton Salt Co. (address, 208 West Washington St., Chicago, Ill.), Manistee, Mich.; the Dow Chemical Co., Midland, Mich.; Pomeroy Salt Corporation (address, Pomeroy, Ohio), Minersville, Ohio; Excelsior Salt Works, Inc., Pomeroy, Ohio (idle, 1936); Texaco Salt Products Co. (address, care of The Texas Co., Houston, Tex.), Tulsa Okla. (idle, 1936); J. Q. Dickinson & Co., Malden, W. Va.; Liverpool Salt Co., Hartford, W. Va.; Ohio River Salt Corporation, Mason, W. Va.; and Westvaco Chlorine Products, Inc., South Charleston, W. Va. It was reported that in 1936 a plant for the manufacture of bromine was under construction at Filer City, Manistee County, Mich., by the Great Lakes Chemical Corporation. No production was reported.

The figures for the value of bromine reported to the Bureau of Mines by the producers represent the value of the bromine f. o. b. plant or shipping point. The average unit value for 1936 was 20 cents a pound compared with 21 cents in 1935. According to Chemical and Metallurgical Engineering, the wholesale price per pound of bulk bromine quoted in the New York market from 1926 to February 1931 was 45 to 47 cents. The price quoted March 1931 and continuing through 1936 was 36 to 38 cents.

Foreign trade.—Imports of bromine, potassium bromide, and sodium bromide, which at one time represented the chief imports of bromine products, are at present only a small part of the total, the largest part being ethylene dibromide used in the manufacture of ethyl gasoline. Importations of ethylene dibromide have fluctuated greatly since 1928 when imports of 283,205 pounds were first reported separately. The largest importation was 3,024,484 pounds in 1930, but in 1933 the quantity had declined to 290,410 pounds. Imports increased to 477,005 pounds in 1935 and jumped to more than twice that quantity in 1936.

The following table shows bromine and bromine compounds imported for consumption in 1936, by countries.

Bromine and bromine compounds imported for consumption in the United States in 1936, by countries

CALCIUM CHLORIDE

The calcium chloride reported in the following table occurs as an original constituent of the natural brine produced in connection with the extraction of salt or salt and bromine from mineral raw materials only. A large output of calcium chloride made by manufacturing processes is not included. The material reported includes calcium chloride mixed with magnesium chlorides or other salts.

Production in 1936 was reported as 125,911 short tons valued at \$1,909,908, an increase of 51 percent in quantity and 84 percent in value over 1935.

Producers of calcium chloride from natural brines in the United States are The California Rock Salt Co. (address, 2465 Hunter St., Los Angeles), Saltus, Calif.; The Dow Chemical Co., Midland, Mich.; Saginaw Salt Products Co., Saginaw, Mich. (idle 1936); Pomeroy Salt Corporation (address, Pomeroy, Ohio), Minersville, Ohio; Excelsior Salt Works, Inc., Pomeroy, Ohio (idle 1936); Texaco Salt Products Co., Tulsa, Okla. (idle 1936); J. Q. Dickinson & Co., Malden, W. Va.; Liverpool Salt Co., Hartford, W. Va.; Ohio River Salt Corporation, Mason, W. Va.; and Westvaco Chlorine Products, Inc., South Charleston, W. Va.

IODINE

Until 1932 little naturally occurring iodine had been produced commercially in the United States. During the war there was a small output of iodine from kelp at plants on the Pacific coast which are no longer active. Extensive experimental work during recent years on processes for the extraction of iodine from brines and oil-well waters has resulted in the establishment of three plants recovering iodine from oil-well brines in Los Angeles County, Calif. These plants were operated in 1936 by the Deepwater Chemical Co., Ltd., Compton, Calif.; the General Salt Co., Ltd., Long Beach, Calif. (sales from stock); and the Io-Dow Chemical Co., Midland, Mich.

Sales of domestic iodine in 1936 were 233,925 pounds valued at \$212,635, a decrease of 5 percent in quantity and 14 percent in value. Imports, which have been held at least partly responsible for restricted production of domestic iodine, increased in 1936 following a sharp decline in 1935.

NATURAL SODIUM COMPOUNDS AND BORON MINERALS

By A. T. COONS

SUMMARY OUTLINE

	Page		Page
Summary.....	1429	Review of operations.....	1431
Domestic production.....	1429	Sales by consuming industries.....	1432
Sodium carbonates and sodium sulphates....	1429	Foreign trade.....	1432
Boron minerals.....	1430		
Manufactured compounds.....	1430		

In 1936 the production of natural sodium compounds (exclusive of sodium chloride) reached a new peak. The total output of sodium carbonates, sodium sulphates, and sodium borates during the year was 468,233 short tons, an increase of 16 percent over 1935. The value of the 1936 production totaled \$7,599,046, a gain of 11 percent over the year preceding.

DOMESTIC PRODUCTION

The quantity and value of the natural sodium compounds (exclusive of common salt) produced in each year from 1932 to 1936 are given in the following table.

Natural sodium compounds (other than NaCl) sold or used by producers in the United States—1932-36

Year	Carbonates ¹		Sulphates ²		Borates ³		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1932.....	55,377	\$888,052	32,204	\$210,342	181,915	\$3,023,844	269,496	\$4,122,238

¹ Soda ash, bicarbonate, sesquicarbonate, and trona.

² Salt cake and Glauber's salt.

³ 1932-33: Borax, kernite, and boric acid (calculated as borax); 1934-36: Borax, kernite, and boric acid (calculated as borax) and also includes a small quantity of colemanite.

⁴ Revised figures.

Prior to 1927 sodium carbonates constituted the bulk of the natural product, but with the introduction of kernite (rasorite) sodium borate became the principal natural sodium compound produced.

Sodium carbonates and sodium sulphates.—In 1936 the sales of sodium carbonates amounted to 102,866 short tons valued at \$1,106,364, an increase of 10 percent in quantity but a decrease of 6 percent in value. The output of sulphates, used as salt cake in the manufacture of glass,

paper, and other commodities, and as Glauber's salt, used chiefly in the preparation of mineral foods for cattle, increased 33 percent in quantity and 22 percent in value compared with 1935. This salt has fluctuated more in annual output than the other sodium salts, producers reporting the imported crude salt (not dutiable), as the principal obstacle to the advancement of the domestic product. A report recently issued by the Bureau of Mines describes a process of obtaining anhydrous sulphate from saline deposits or brines.¹

Figure 118 gives the quantity and value of natural sodium compounds produced in the United States, 1927-36.

Boron minerals.—The output of boron minerals reached a new peak in 1936. Reports of producers to the Bureau of Mines indicate that the total production during the year amounted to 313,759 short tons valued at \$6,156,123, increases of 15 percent in quantity and 14 percent in value over 1935. Before 1927 the source of all the borax except that

FIGURE 118.—Quantity and value of natural sodium compounds (other than NaCl) produced in the United States, 1927-36.

made at Searles Lake and Owens Lake was colemanite (calcium borate) mined in California and Nevada. In 1927 kernite mined in Kern County, Calif., replaced colemanite, production of which virtually ceased after 1927, although small shipments were made through 1930, and small shipments (included with borates) have been made in 1934, 1935, and 1936.

Manufactured compounds.—Besides these products of natural brines, a large output of soda ash made by the ammonia-soda process and a small quantity of electrolytic soda is manufactured from common salt brine. In 1935, according to the Bureau of the Census, 17 establishments produced 2,508,559 short tons of soda ash. Of the total, 637,224 tons were consumed by the producing establishments, and 1,871,335 tons valued at \$28,424,750, were sold.

¹ Conley, J. E., and Partridge, Everett P., *Anhydrous Sodium Sulphate from Saline Deposits or Brines by a Four-Stage Process: Report of Investigations 3299*, Bureau of Mines, 1936, 18 pp.

In the same way, natural sodium sulphates account for a relatively small part of the total domestic production, most of which is recovered at chemical works. Compared with a total output of natural sodium sulphate of 38,706 short tons valued at \$275,943 in 1935, the Bureau of the Census reports the production of 169,197 tons of salt cake valued at \$1,857,435; 27,933 tons of niter cake (of which 9,348 tons was consumed in the establishment and 18,585 tons valued at \$342,132 was sold; 23,609 tons of refined anhydrous sodium sulphate valued at \$457,890; and 40,735 tons of Glauber's salt valued at \$549,220. The aggregate value of these items is \$3,206,677.

REVIEW OF OPERATIONS

In 1936 most of the material included in the sales of sodium carbonate was soda ash—normal sodium carbonate (Na_2CO_3)—produced in California from the waters of Owens Lake in Inyo County by the Natural Soda Products Co. at Keeler, and from the waters of Searles Lake in San Bernardino County by the American Potash & Chemical Co. at Trona and the West End Chemical Co. at Westend. Sodium bicarbonate (NaHCO_3) and trona, a mixture of soda ash and bicarbonate, were produced by the Natural Soda Products Co., and bicarbonate and sesquicarbonate were reported by the Pacific Alkali Co. at Bartlett.

Sodium sulphate, as salt cake (Na_2SO_4), was produced at Trona on Searles Lake, San Bernardino County, Calif., by the American Potash & Chemical Co. in 1936 for the third year. Production at this plant largely accounts for the continued increase in the output of this salt. A considerable quantity was also produced near Monahans, Ward County, Tex., by the Ozark Chemical Co., of Tulsa, Okla., and sales were made from stock on hand at the deposit of the Rhodes Alkali & Chemical Corporation near Mina, Mineral County, Nev. A plant for the production of natural sodium compounds was in the process of erection in 1936 near Wilson Creek, Grant County, Wash., by the Sodium Products Co., but no product has been marketed. The Salt Lake Sodium Products Co., Salt Lake City, Utah, had under construction at Saltair, Salt Lake County, a plant for the production of Glauber's salt and anhydrous sodium sulphate. Hydrated sodium sulphate ($\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$) (Glauber's salt) was produced near Casper, Natrona County, Wyo., by W. E. Pratt on the Pratt and Gill deposits. The Iowa Soda Products Co. mined Glauber's salt near Rawlins, Carbon County, Wyo.

The sodium borate produced in 1936 includes borax ($\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O}$) obtained in California from Searles Lake brines in San Bernardino County by the American Potash & Chemical Co. at Trona and the West End Chemical Co. at Westend and from Owens Lake brines in Inyo County by the Pacific Alkali Co. at Bartlett. Sodium borate, as kernite ($\text{Na}_2\text{B}_4\text{O}_7 \cdot 4\text{H}_2\text{O}$), was produced in Kern County, Calif., by the Pacific Coast Borax Co. near Mojave. Boric acid also was produced by the American Potash & Chemical Co.; this product, calculated as borax, is included with sodium borate in the figures for sales from 1932 to 1936. Colemanite (calcium borate) was produced in small quantity near Shoshone, Inyo County, by the United States Borax Co.

SALES BY CONSUMING INDUSTRIES

A recent analysis made by Chemical and Metallurgical Engineering² indicates that in 1936 more than a third (38 percent) of the soda-ash sales were made to producers of heavy chemicals and manufacturers of dyes and organic chemicals. The glass and ceramic industries accounted for another 38 percent of the total sales. Other important consumers of soda ash were the soap and glycerine manufacturers, the textile-processing mills, and the pulp and paper industry.

Three industries—pulp and paper, textile processing, and glass and ceramics—absorbed more than 86 percent of the sales of sodium sulphates in 1936.

The following table gives the percentage distribution of sales of soda ash and sodium sulphates in 1936, as estimated by Chemical and Metallurgical Engineering.

Estimated distribution of sales of soda ash and sodium sulphates in 1936, by consuming industries

¹ Includes plastics and resins, wood chemicals and naval stores, manufactured gas and coke, oils, fats, and greases, paints and pigments, rubber goods, and sugar and food products.

FOREIGN TRADE³

Exports and imports of sodium sulphate and borax are given in the following tables; figures for sodium carbonates are not given, as they are relatively insignificant in comparison with domestic sales and consist wholly of manufactured salts.

Exports of sodium sulphate were small in 1933-36 and were not reported separately. The total imports of sodium sulphate in 1936 were nearly one and one-half times more than in 1935. Crude salt cake imported increased 37 percent in quantity and 39 percent in value; crystallized sodium sulphate (Glauber's salt) increased 4 percent in quantity and 3 percent in value; and the anhydrous salt increased 105 percent in quantity and 98 percent in value.

Exports of sodium borate decreased 11 percent in quantity and 4 percent in value, and the quantity of sodium borate imported was two and one-half times more than in 1935.

³ Chemical and Metallurgical Engineering, vol. 44, no. 2, February 1937.

¹ Less than 1 ton.

Imports of sodium sulphate from Germany, which represented 81 percent of the total imported in 1936, increased 48 percent compared with 1935. Imports of this commodity from Canada, although relatively small, were over seven times more than in 1935, and those from Netherlands nearly three times more. Imports from Belgium and Chile, on the other hand, decreased. In 1934 and 1935 there were imports of sodium sulphate from U. S. S. R. (Russia), but none was reported for 1936. By far the bulk of the imported salt cake is entered at Gulf ports for use by the growing kraft-paper industry of the South.

Market.....	1436	Lesser gems.....	1440
Cutting.....	1437	Bibliography.....	1440

The jewelry industry throughout the world improved markedly in 1936, but retail sales in the United States, estimated at \$310,000,000, were only 58 percent of those in 1929. Prices advanced in the latter half of the year owing to the increase in prices of fine gems and platinum. Improved financial conditions stimulated sales of fine jewelry in 1936, which comprised a larger proportion of total sales than in 1935.

If the demand for fine-colored stones continues, increased production will be necessary to avoid a shortage. During the year a number of exceptionally fine jewels were exhibited in the larger cities throughout the country, thereby increasing the interest of the public in gems.

Fashions in jewels.—Women's gowns in 1936 were of fine fabrics and required real gems as well as other luxurious accessories. The fashionable world has become "jewel-minded", and even with sport clothes, jewels are considered smart. For more than a year the use of gold has been increasing at the expense of platinum. Bracelets, clips, necklaces, and earrings have been particularly popular, the last frequently being clips covering the lobe of the ear. Jeweled flowers in the form of pins are both beautiful and expensive. Diamond, emerald, sapphire, and ruby are of course the most desired of all gems; however, star sapphire and aquamarine are gaining in popularity, as are also, to a smaller extent, topaz, amethyst, and turquoise. Men continue to favor star sapphire, cat's-eye, and star ruby.

Domestic production.—The search for precious stones in the United States in 1936 was more actively pursued than in the past 5 or 6 years, and the total value of products probably approached \$12,500. Lee F. Hand is reported to have produced 545 pounds of turquoise worth about \$4,500 from the Snow Storm claim, Royston district, Nevada. The Mildred and Marguerite properties in the Crow Springs district and the Reik mine near Columbus, Nev., as well as properties in Mineral Park, Ariz., are also reported to have produced turquoise. Some 10 tons of moss and other agate were collected in Montana, and agate and jasper were produced in California. A considerable amount of agatized wood was recovered from private lands around the Petrified Forest National Monument, Ariz., and some 3,250 pounds of irides-

cent obsidian was produced in Modoc County, Calif. About 800 pounds of rose quartz of gem quality was mined in the Black Hills of South Dakota. Walter W. Bradley reports that a diamond weighing $\frac{3}{4}$ carat was recovered in Butte County, Calif. In addition, the following gem stones were produced during the year: Ruby (Tiger, Ga.); sapphire (Macon County, Ga., and Montana); aquamarine (Park County, Colo.); opal (Nevada and San Bernardino County, Calif.); topaz (Thomas Range, Juab County, Utah, and Fresno County, Calif.), and blue topaz (Teller and Park Counties, Colo.); garnet (Fresno County, Calif., Emerald Creek 12 miles southwest of Fernwood, Idaho; Thomas Range, Juab County, Utah; Montana; Colorado; Black Hills, South Dakota, and North Carolina (rhodolite)); zircon (Fresno County, Calif.); prase opal (Sonoma County, Calif.); amazonite (Florissant district, Colorado); amethyst (Lorimer County, Colo.); and rock crystal (Arkansas).

Imports.—According to the Bureau of Foreign and Domestic Commerce imports of precious and imitation stones into the United States in 1936 totaled \$38,146,113, an increase of 38 percent over 1935. Details are shown in the following tabulation:

	Carats	Value
Diamonds:		
Rough, uncut, duty free.....	97, 677	\$6, 230, 902

Marcasites, dutiable.....		32, 768

DIAMOND

With the United States and other countries again purchasing substantial quantities of stones, the diamond industry improved beyond expectations in 1936; virtually all indicators of the industry showed gains of 25 to 45 percent over 1935. The improvement was due largely to the better world industrial outlook and to a marked increase in demand for industrial stones, as industry now absorbs many stones that 20 years ago would have been cut as jewels. Speculation and investment buying were smaller factors in the increase. Notwithstanding a small increase in production, stocks of rough diamonds decreased markedly. Stocks of polished goods were also low. Prices of both rough and cut diamonds advanced during 1936.

Share dealings.—Trading in shares of diamond-mining companies was active, especially in the second half of 1936. Six representative stocks advanced an average of 86 percent during the year. At the end of the year they were 65 percent of their high (1927) and 650 percent of their low (1932). Of the 15 more important stocks, 11 paid dividends.

Market.—The value of sales of rough diamonds by the Diamond Trading Co. was about £8,500,000 in 1936, a 36-percent gain over 1935. The market was broad; purchasers came from all parts of the world, and all types of stones were sold. Good-quality large stones were scarce at the end of the year.

The market for polished stones was animated, and in the last half of 1936 even the cutters of small diamonds were making reasonable profits. India and the United States were the principal buyers, while Japan's 1936 purchases were more than tenfold those of 1934.

Investment buying of fine stones of more than 1 carat was worldwide; the Continent was a particularly large purchaser.

Cutting.—The status of the diamond-cutting industry improved markedly in 1936, and the cutting centers of Belgium, Holland, and Germany showed a more conciliatory attitude toward one another. Better prices permitted the masters to make profits, employment increased, and the men enjoyed better wages and shorter hours. At the end of the year about 310 cutters were employed in the United States.

Imports.—Diamond imports into the United States in 1936, by countries, were as follows:

Diamonds imported into the United States in 1936, by countries ¹

¹ Compiled from records of the Bureau of Foreign and Domestic Commerce.

Taxes and tariffs.—On June 22, 1936, the 10-percent excise tax on sales of jewelry items valued at more than \$25 was repealed. In September Italy placed a "temporary" duty of 20 percent on diamond imports.

World production.—World production of diamonds in 1936 approximated 8,296,900 carats (1.829 tons) worth about \$35,600,000. Compared to 1935 this is an increase of about 9 percent in quantity and 14 percent in value. As the South African pipe mines operated only on a small scale, the alluvial mines accounted for some 96 percent of the carats and 86 percent of the value.

The following table gives, as accurately as available statistics permit, world diamond production for the past 5 years:

World production of diamonds, 1932-36, by countries, in carats

Country	1932	1933	1934	1935	1936

¹ Estimated.² Exports year ended Mar. 31.³ Exports.⁴ Includes a small quantity of diamonds recovered from re-treatment of tailings.

¹ 1932-34, includes Borneo, India, New South Wales, and, in certain years, French Equatorial Africa, Rhodesia, United States (Arkansas and California), and Venezuela; 1935, Australia, Borneo, French West Africa, India, Nigeria, and Venezuela; 1936, Borneo, India, Nigeria, Rhodesia, and Venezuela.

The increase in production in 1936 came from the pipe mines of South Africa and the alluvial mines of the Belgian Congo, Angola, and Sierra Leone, that is, from mines administered by interests closely allied to the Diamond Corporation. The Central African field (Belgian Congo-Angola), which for 6 years has been the largest producer by weight, in 1936 for the first time surpassed South Africa in value of production as well. French Africa made its initial appearance as a producer of some importance, whereas the production of the South African alluvial fields continued to decrease. Less than 40 percent of the total production was of gem quality; the increase was in industrial stones.

Industrial diamonds.—The rapid development of the use of hard alloys in industry in general and particularly in armaments programs has caused a great expansion in the use of abrasive diamonds. The United States, Great Britain, Germany, and Russia are the principal consumers. The chief use is trueing abrasive wheels, but diamond drills, diamond dies, wheels in which diamond or diamond dust are bonded in either bakelite or metal, diamond-set tools, diamond-bonded tools, and many other uses are also important. Some years ago bort largely supplanted carbonado in most drilling, but recently both types of diamonds have been set in some bits. Some bitmakers are now molding bits, the diamonds being "set" in molten metal. The use of "common goods" (cheaper than bort) in diamond drilling is increasing. Experiments continue to supplant rock drills with diamond drills in driving drifts, and diamond drills are used in stoping at the Noranda mine. On the Rand experiments are being conducted with a diamond-impregnated wheel built on the principle of a coal cutter, with which the "banket" is sliced.

It should be emphasized that 50 to 60 percent of a normal year's production of abrasive diamonds is destroyed in use in various industries.

The trade obtains industrial diamonds from three principal sources: (1) Direct from the Diamond Trading Co. or its affiliates; (2) from that part of cutters' and brokers' purchases from the company not suitable for gem stones or too "knotty" to cut easily; and (3) from "outside" sources, notably the Brazilian carbonado production. At present the Diamond Trading Co. is a more important source of industrial stones than formerly due to two factors: First, many stones once used in low-priced jewelry are now used industrially; and, second, carbonados now make up a smaller part of the total supply of industrial diamonds than a decade ago. Bahia's exports of carbonados in 1935 approximated 21,000 carats valued at \$630,000 (in 1934, about 14,200 carats valued at \$300,000).

Because of the greatly increased demand and the fact that most of the South African pipe mines have been shut down and that the Brazilian carbonado production has been subnormal, there has already been a shortage in supply of certain types of industrial stones. As a result of this scarcity some industrial diamonds were selling at pre-depression prices in 1936. Large industrial stones (over 2 carats) were, however, somewhat cheaper than in 1929, and carbonado was much cheaper. The price of crushing bort, notwithstanding increased use, remained steady.

Imports of industrial diamonds into the United States during the past 5 years are as follows:

*Industrial diamonds (glaziers', engravers', and miners') imported into the United States, 1932-36*¹

EMERALD, RUBY, AND SAPPHIRE

The Colombian Government abandoned the Muzo emerald mine about 5 years ago and in 1932 opened a new mine 3 miles distant. For the past 3 years the average annual production is said to have been about 400,000 carats worth 400,000 pesos. Some 300 workmen and a guard of 60 to 100 soldiers are employed. A few emeralds are recovered from the beryl pegmatites and surrounding schists near Gravelotte, northeastern Transvaal. Sales in 1935 were 148,451 carats worth £10,756.

Burma increased its ruby production considerably in 1935. The total output was 105,484 carats worth 114,063 rupees (in 1934, 21,622 carats); 2,431 carats of sapphires and 6,687 carats of spinels were produced as byproducts.

The Padar district of Kashmir, where operations at the sapphire mines were resumed in 1933, produced about 800,000 carats in 1935 compared with 1,075,000 carats in 1934. The total Indian output in 1935 was 904,571 carats. Ceylon's production of precious stones (largely sapphire) is apparently increasing; some estimates place it as high as Rs.2,000,000 in 1935. The Ratnapura, Matara, and Kandy

districts were especially active. Sapphire and beryl were recently discovered in abundance in the last two districts named. For some years the American Gem Mining Syndicate has operated its mine near Philipsburg, Mont., for industrial sapphires only. Production in 1936 was 17,200 ounces worth about \$25,000. Sapphire was the only gem produced in Queensland in 1935, and sales totaled £1,804 15s. compared with £3,055 in 1934. The mine is at Sapphire. The Belgian Congo sapphire mines of the *Minière des Grands Lacs* have not been worked for several years.

LESSER GEMS

In 1935 Prussia produced 102,489 kilos of amber and purchased 9,484 kilos from small producers (in 1934, 107,026 and 9,165 kilos, respectively); 22,900 kilos valued at 258,000 RM were exported in 1935, or the highest exports since 1931. Most of the amber output was used industrially. In 1935 Burma produced 18.57 cwt. of amber valued by the Government at \$777 and 1,264.75 cwt. of jadeite valued at \$71,465. Meerschaum mining at Eskisehir, Asia Minor, has been encouraged by the Eti-Bank in connection with the Turkish 5-year plan. In pre-war days about 280 metric tons a year were exported, but less than 28 tons were shipped in 1935. Ninety percent of the output is exported. In 1935, 9,000 pounds of tiger-eye were exported from South Africa. The lighter-colored varieties occur in slabs 9 to 12 inches long, but the darker-colored only in smaller pieces. Brazil produces six types of quartz, of which 90 percent comes from Minas Geraes, and exports of rock crystal have averaged 5 tons yearly for the past 7 years. The United States and Japan are the principal consumers. In 1935, 230,862 kilograms valued at 998,701 paper milreis were exported. Madagascar continues to export much low-priced gem material to France, Japan, the Netherlands, Great Britain, and Czechoslovakia. In addition to 20,000 carats of precious stones about 1½ tons of garnet, amethyst, beryl, optical rock crystal, rose quartz, and chalcedony were exported in 1935. South-West Africa in 1935 exported gems other than diamonds valued at £1,818 to Germany. The mandated area is a source of aquamarine and heliodore, red and green tourmaline, topaz, and almandine garnet.

GRAPHITE

The graphite-mining industry in the United States remained virtually dormant in 1936. There was, however, a steady increase in consumption throughout the world. Domestic flake graphite is not wanted by crucible makers, and virtually the entire dry-battery market, formerly a profitable outlet for American producers of flake graphite, has been lost to manufactured graphite. Moreover, dry-battery sales have declined sharply owing to the almost Nation-wide use of light-socket power instead of dry batteries for radios. For most other uses manufactured graphite or imported graphites are either cheaper or better. The opinion is widely held that a domestic industry could be created on a substantial scale, provided leading consumers could be induced to make a real effort to readjust their manufacturing operations so as to use the domestic product, but the fact is that there never has been enough incentive for them to undertake the requisite research. Except perhaps in wartimes a variety of good-quality graphite has always been available in abundance abroad, and the price of this raw material ordinarily represents too small a proportion of the cost of making and selling graphite products to encourage domestic consumers to experiment with domestic material, even if they felt they could get it cheaper.

No output of crystalline graphite was reported to the Bureau of Mines in 1936 from the various graphite-producing areas of the United States, although some sales were made locally by the Crystal Graphite Co., Dillon, Mont. The Carson Black Lead Co., Oakland, Calif., mined amorphous graphite for paint from its mine at Carson, Nev.

Artificial graphite is manufactured principally by the Acheson Graphite Corporation (30 East 42d St., New York, N. Y.) at Niagara Falls, N. Y., but is also produced as a byproduct of the manufacture of silicon carbide. The Acheson Graphite Corporation is likewise the

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

leading manufacturer of graphitized electrodes, although these are produced at St. Marys, Pa., by several other concerns.

The Trade Agreement with France, effective June 15, 1936, reduced the duty on flake graphite from 1.65 cents a pound to 30 percent ad valorem with the proviso that the new rate should be not less than 0.825 cent nor more than 1.65 cents. The ad-valorem rates on carbons electrodes, and other graphite or carbon products under the Tariff Act of 1930 (par. 216) were reduced by one-third; the duty on small arc-light electrodes was cut from 60 to 40 percent and that on other products from 45 to 30 percent of the foreign market value.

¹ Graphite, crude, refined, and manufactures.

² Graphite, crude, refined, and blended.

Graphite is found in almost every country and is produced commercially in a score of countries; nevertheless 85 percent of the world supply comes from half a dozen countries. On the basis of tonnage alone, Czechoslovakia, Austria, Chosen, and Germany (Bavaria) have been the largest producers of graphite, but their product is chiefly of the amorphous variety and consequently not so valuable as that of Madagascar and Ceylon, which produce flake and vein graphite, respectively. However, amorphous graphite is used relatively more and for a greater variety of purposes in Europe than in the United States, where consumption is divided more or less evenly among crystalline, amorphous, and artificial graphites.

Conditions in leading foreign producing countries have been reviewed briefly in two previous volumes of the Minerals Yearbook. Among new developments it is of interest to record here an all-time record output in Mexico, which produced 10,732 short tons valued at \$107,134 in 1936, topping the previous peak by almost 30 percent. Canada's Black Donald mine in Renfrew County, Ontario, also had a good year; the value of its output increased to \$92,820 from \$79,781 in 1935. Heretofore the product of this mine has been used mainly for lubricants and foundry purposes, but it is now being employed in pencil making, a market that at one time was supplied almost exclusively by producers of Mexican graphite.

World production of natural graphite, 1927-35, in metric tons

As most graphite business is done by private negotiation it is difficult to report prices. The variety of grades and kinds adds to the difficulty. During 1936 the American market was steady, and prices remained virtually unchanged. Madagascar flake averaged a trifle under and Ceylon lump a trifle over 5 cents a pound, while amorphous grades ranged from \$10 to \$20 a short ton.

London market quotations likewise varied little from the 1935 levels. Through 1936 Madagascar flake, 85 to 90 percent, duty paid, usually ranged from £18 to £20 a long ton, although lifting occasionally to £21. Ceylon lump, 90 percent, began the year at £11 to £12 a long ton and after stiffening perceptibly stood at £11 to £13 a ton at the end of the year. In American currency the final quotations were equivalent to about 4.15 cents per pound for Madagascar flake and 2.65 cents per pound for the Ceylon product. The former figure includes the duty collected on imports into the United Kingdom from countries outside of the British Empire.

GREENSAND

The best grade of greensand, screened and bagged, has been quoted in Engineering and Mining Journal Metal and Mineral Markets at \$20 per short ton, f. o. b. cars in New Jersey, in carload lots. Production, recently reported by five companies, consists mostly of processed material used for water softening. The quantities used for fertilizer have dwindled to insignificant proportions.

KYANITE

The domestic kyanite industry is still in the development stage, and for 1936 there is little to record beyond a steady expansion in demand and further improvement in concentrating technique. Statistics of production are not collected by the Bureau of Mines, but output in North Carolina and Georgia increased, and larger quantities were imported from India.

Operations of Celo Mines, Inc. (Burnsville, N. C.), a leading producer, were described by Mattson² and, in more detail, by Trauffer.³ At this plant the concentrating process is a combination of magnetic separation, screening, and air tabling. Garnet concentrates are a byproduct, and the complexity of the ore is indicated by the fact that in a single hand specimen 26 different minerals have been identified with a microscope.

Wet concentration is employed in Georgia where, according to Smith, State geologist,⁴ the Georgia-Carolina Minerals Corporation, in addition to its placer operations at Clarkesville, started in 1936 the recovery of kyanite, mica, and other products from partly weathered kyanite-mica schist at two places in Habersham County.

The principal market for Georgia kyanite is glassworks refractories, and the price, f. o. b. mines, has been about \$30 a ton. North Carolina

³ Trauffer, W. E., Materials Move by Gravity in Kyanite Plant on North Carolina Mountaintop; Pit and Quarry, vol. 28, no. 9, 1936, pp. 44-48.

⁴ Smith, E. W., The Kyanite Industry of Georgia; Am. Inst. Min. and Met. Eng., Tech. Pub. 742, 1936 11 pp.

kyanite has been used for various ceramic purposes, while the imported material has been used extensively in the manufacture of refractory brick. Some research has been directed toward utilizing the expansive property of kyanite to offset shrinkage of high-alumina refractories, and experimental results have been promising. Large increase in the use of kyanite, however, seems to be contingent upon lower prices, probably \$15 a ton or less. With small-scale operations the cost is likely to be too high for the product to be sold at any such figure, but once an adequate market is assured large-scale operations can probably be developed to meet the requirement for low-priced material. One objection to flotation concentrates is that the brickmakers demand a large proportion of coarse material, but possibly this objection can be overcome by sintering the fine kyanite so as to make a suitable grog. Experiments with this end in view are being conducted at the Bureau of Mines station at New Brunswick, N. J.

LITHIUM MINERALS

Lithium is rather widely distributed in nature,⁴ and nearly a dozen minerals contain lithium as a more or less essential constituent. Only three minerals, however, are recognized as industrially available sources of lithium, and none of these contains more than small percentages of the element. Amblygonite, $2\text{LiF} \cdot \text{Al}_2\text{O}_3 \cdot \text{P}_2\text{O}_5$, the richest ore of lithium, theoretically contains only 10 percent lithia (Li_2O) and commercially only about 9 percent. Spodumene, $\text{Li}_2\text{O} \cdot \text{Al}_2\text{O}_3 \cdot 4\text{SiO}_2$, ordinarily contains less than 7 percent Li_2O and formerly, although mined by one company for its own use, was not easily salable; with increased demand for lithium, however, it promises soon to become the principal source. The theoretical formula of lepidolite, $3\text{Li}_2\text{O} \cdot 2\text{K}_2\text{O} \cdot 3\text{Al}_2\text{O}_3 \cdot 12\text{SiO}_2 \cdot 8\text{F}$, indicates a lithia content of more than 6 percent, but 4 percent is about the top limit for commercial shipments. All three minerals characteristically occur only in pegmatites. Amblygonite and spodumene both resemble ordinary feldspar in appearance, and lepidolite is one of the micas which occurs, however, as pink to purple scaly masses rather than in large sheets.

The uses of lithium metal and its salts are outlined briefly in the chapter on Minor Metals in this volume of Minerals Yearbook. Of chief interest is the growing use of lithium chloride in air conditioning. Nevertheless, lithiated waters and medicinal preparations still account for a relatively large part of the consumption, and the uses of the metal are not unimportant. Lithium hydroxide is used in Edison storage batteries, and some lithium salts may be used in pyrotechnics owing to the red coloration they impart to flame, although most red flares are produced by strontium compounds. Lepidolite has been used in making enamels and special glasses, and it is possible that spodumene may be used as a ceramic raw material after preliminary calcination to convert it into the beta form which does not expand greatly upon further heating.

Domestic supplies of amblygonite and spodumene have come principally from South Dakota, although small quantities have been mined in California. Spodumene also occurs in Maine and North Carolina, apparently in large amounts. Lepidolite was mined

⁴ Stock, Lester W., The Distribution of Lithium in Rocks and Minerals as Revealed by Quantitative Spectrum Analysis: *Am. Mineral.*, vol. 21, no. 12, 1936, p. 7.

extensively in California and New Mexico from 1920 to 1930. The output of lithium minerals in the United States reached a maximum of 11,696 tons valued at \$173,002 in 1920, of which most was lepidolite. In 1930 only 1,797 tons valued at \$56,327 were reported. After further declines in 1931 and 1932, for which years figures cannot be published, mining of both amblygonite and spodumene was resumed in the South Dakota field. Statistics covering the domestic production of lithium minerals for 1918 to 1928, inclusive, have been published in Bureau of Mines Information Circular 6215 on caesium, rubidium, and lithium. Available data for later years follow:

Lithium minerals produced and shipped in the United States, 1929-36

1932.....	2	(¹)	(¹)	1936.....	6	1,239	25,273

¹ Bureau of Mines not at liberty to publish figures.

The Bureau of Mines recently has worked actively toward creating a spodumene-mining industry in North Carolina. The disseminated deposits near Kings Mountain have been shown by Hess ⁶ to afford one of the world's principal sources of potential supply of lithium. Methods for concentrating this and similar material known to occur in other States have been investigated by Will H. Coghill at the Bureau's station at Rolla, Mo., and by O. C. Ralston at its New Brunswick (N. J.) station. At the latter station a novel method of concentration has been evolved ⁷ that is so simple it can be done by farmers with home-made equipment. The Southern Mining & Milling Co., Clarkesville, Ga., began mining this ore and proposed to install a furnace for beneficiating it in 1937.

Prices of amblygonite tended slightly upward in 1936. Although still quoted nominally at \$34 to \$35 per short ton f. o. b. South Dakota mines, actual sales were made at prices up to \$40 a ton for 8- to 9-percent material. The price of spodumene is about \$20 f. o. b. South Dakota mines, and \$35 can probably be obtained for 7-percent material delivered at eastern consuming points. Lepidolite is quoted in Engineering and Mining Journal Metal and Mineral Markets at \$20 to \$25 per ton (basing point not stated). Sales of domestic lepidolite in 1936 were insignificant, and South African and Canadian deliveries likewise seem to have been quite small.

MINERAL WOOL

Production figures for mineral wool are not collected by the Bureau of Mines but have recently been published biennially by the Bureau of the Census, which reported a total value of \$7,672,096 for the production of "mineral wool (other than asbestos) for building insulation" in 1935 compared with \$1,714,171 in 1933, \$2,873,230 in 1931, and \$2,377,324 in 1929.

⁶ Hess, Frank L., *Lithium in North Carolina*: Eng. and Min. Jour., vol. 137, no. 7, 1936, pp. 339-342.

⁷ Fraas, Foster, and Ralston, O. C., *Beneficiation of Spodumene by Decrepitation*: Bureau of Mines Report of Investigations, 3336, February 1937, 13 pp.

Slag wool was made in Germany in 1870, and the rock-wool industry was established in Indiana by 1897, but the great growth of the industry has taken place within the last decade. In 1900 the reported production of mineral-wool products was 6,002 tons valued at \$60,320 or about \$10 a ton. Ten years later it had grown to 8,408 tons valued at \$84,012. The census of manufactures for 1929 reports the value only of mineral-wool products as \$2,377,324, which came from eight producers—two in Indiana and one each in California, Illinois, Michigan, New Jersey, Ohio, and Wisconsin. Since the decline in 1933 the industry has forged ahead with remarkable rapidity. Census figures for 1935 show 111,745 tons of rock wool valued at \$3,357,526, 31,648 tons of slag wool valued at \$1,184,946, and "other" wool (mostly glass wool) valued at \$3,129,624. No figures are given on the tonnage of glass wool, but as this product is worth a great deal more per ton than ordinary rock or slag wool the data indicate an aggregate production of all kinds of mineral wool of less than 200,000 tons in 1935. Unofficial estimates indicate that the total output in 1936 increased to more than 400,000 tons, but this figure cannot be verified. However, it may be noted that the number of plants increased in 1936 (at least 50 plants and perhaps more are now engaged in making these products), and most plants were working nearly to capacity. The National Association of Rock and Slag Wool Industries serves the industry.

Roughly two-thirds of the domestic output of mineral wool is used for building insulation, and much of it is employed for insulating existing homes. Notwithstanding the rapid growth in production and the increased output of competitive materials, such as vermiculite, there is no indication at present of approaching saturation of the market for mineral wool. A recent canvass of architects by a leading journal⁸ drew a 100-percent affirmative answer in favor of house insulation against heat and cold, even for relatively small one-family dwellings. All types of insulation—mineral wool, aluminum foil, and wallboards—were popular. Florida and Louisiana architects stressed the importance of insulation against sun heat. This survey tends to confirm the trend of mineral-wool manufacture. Another factor favoring greater use of insulating materials is air conditioning which, after making rapid progress in commercial buildings, is generally expected to work down into the residential field. So long as the American people have money to spend on making their homes comfortable, a growing increment of such expenditures will be available for the purchase of insulating materials.

In most tests mineral wool stands out as having the highest insulating value among materials in general use for house fill. In *Minerals Yearbook*, 1936 (p. 1067) a serious error was made in reporting the results of tests by the National Research Laboratories, Ottawa.⁹ The real message of the tabulated figures was that rock wool is a far better insulator than asbestos or serpentine in any of the forms tested.

⁸ *Architectural Record*, *The Record* scans the Field: Vol. 81, no. 3, 1937, p. BT-11.

⁹ Niven, C. D., *The Thermal Conductivity of Sundry Materials*: Canadian Jour. Research, vol. 13, no. 1, sec. A, July 1936, pp. 16-18.

In a recent Letter Circular (LC-471, June 9, 1936), the National Bureau of Standards, Washington, lists a number of publications¹⁰ which contain specific information as to insulation problems.

MONAZITE

As the use of cerium alloys in sparking flints for gas and cigar lighters has increased greatly during the last decade or two, it has been thought that this might soon revive the demand for monazite. This is a vain hope, for, as noted in the discussion of rare earths in the Minor Metals chapter of this volume, accumulations of cerium residues at thorium-nitrate and gas-mantle works throughout the world are large enough to supply demands for three-quarters of a century at the present rate of consumption. The magnitude of these accumulations can be estimated only roughly, but the figures show that the total consumption of monazite since 1893, mostly for gas-mantle making, has been a little short of 100,000 tons, of which more than 30 percent was cerium oxide and nearly 30 percent more comprised lanthana, didymia, and other rare-earth oxides. Only a small fraction of this 60,000 tons of rare-earth oxides has been utilized by the gas-mantle and other consuming industries.

No domestic production of monazite has been reported since 1925, when 2,000 pounds were recovered as a joint product in Florida beach-sand operations for ilmenite and zircon. British India captured most of the monazite market more than 20 years ago, but with gas-mantle requirements scarcely 10 percent of their one-time volume world demand for monazite has dropped to only a fraction of its former level, which is indicated by the maximum production of 7,392 short tons in 1909. Although all the thorium nitrate needed for gas mantles today could be extracted from about 300 tons of good monazite, actual demand has not fallen quite as much as this might indicate. The mineral has other uses, most important of which apparently is the manufacture of flaming-arc carbons. Due to the vogue of light therapy and the increase in sales of heat-ray lamps for use in American homes, imports of monazite into the United States have expanded again during the last few years.

The price of monazite has fluctuated widely, but until about 1929 it rarely dropped below \$20 or \$25 a unit of thoria content, or about \$120 a ton for 6-percent ore. During the World War and again in 1920 it cost about double these figures, delivered at New York. Quotations of \$60 a ton, however, were reported by *Engineering and Mining Journal* during 1930 for monazite containing a minimum of 6 percent thoria. In July 1932 the basis of quotation was advanced to 8 percent minimum, and less than a year later the quotation was dropped to \$50 a ton. The price increased to \$60 in 1934, at which figure it remained until the second quarter of 1936 when it was broadened from \$60 to \$75 a ton.

OLIVINE

Olivine, a natural magnesium silicate of good refractory properties, is abundant in North Carolina where it is produced and shipped by at least three companies. Commercial shipments began about 1930 but were small. Although a relatively new product it seems to be used in increasing quantities by steel companies, and favorable reports have been received as to its performance, particularly in back walls of open-hearth furnaces. Substantial quantities of olivine are also used in shaped refractories, sold under the trade name "Forsterite", which seem to have been satisfactory in the steel industry for open-hearth bulkheads and in various nonferrous metallurgical furnaces for roofs and walls above the slag line. Trials are in progress to test its use for rotary-kiln linings. Several installations of complete burning zones lined with Forsterite brick are now in service in kilns burning portland cement and dolomite. Statistics of production or consumption of olivine are not available for publication, but they have exceeded 5 carloads monthly.

Although Forsterite refractories were introduced in 1933 a considerable tonnage was not shipped until 1935; several thousand tons of these refractories have been shipped in each of the last 2 years.

Forsterite bricks are made by adding a small amount of magnesite to olivine so that their composition approaches that of natural forsterite ($2\text{MgO} \cdot \text{SiO}_2$). The manufacture of these refractories, which has been fully described in technical literature,¹¹ is covered by United States patents, and a working arrangement has been made with Prof. V. M. Goldschmidt, who worked on similar materials in Norway in the laboratory of the Government Raw Material Committee in co-operation with the Norwegian Ministry of Trade and Industry. The combination of magnesia with olivine produces a high-temperature-load-carrying refractory. The talc, serpentine, and small amounts of other hydrous impurities that commonly occur in olivine do not tend to lower the softening point.

Cut blocks of natural olivine are available, but sales to date have been largely of crushed rock or rubble. The rock has no definite cleavage, and costs of cutting blocks have been prohibitively high, running from \$30 to \$40 a ton. Of potential interest is the use of olivine aggregate, prepared in three suitable sizes, with high-alumina cements to make a refractory material that can be cast in place like ordinary concrete.

Owing to the relatively low cost of mining olivine and the fact that the deposits are situated in the eastern part of the United States

¹¹ Birch, R. E., and Harvey, F. A., *Forsterite and Other Magnesium Silicates as Refractories*: Jour. Am. Ceram. Soc., vol. 18, no. 6, 1935, pp. 176-192.

reasonably near consuming centers, it is one of the cheapest high-duty refractories capable of withstanding basic slags. For example, at \$8 a ton f. o. b. mines, it costs little more than one-third as much as dead-burned magnesite.

Extensive deposits of olivine in the State of Washington likewise may be utilized in the manufacture of firebrick and other refractory material. Deposits occur on Cypress Island, and more than 40 square miles of olivine rock are exposed in the Twin Sisters Mountains east of Bellingham. Investigations at the Northwest Experiment Station of the Bureau of Mines in cooperation with the College of Mines, University of Washington, showed that commercial quantities of this dunite can be secured which contain 47 to 49 percent magnesia. Refractory tests showed a pyrometric cone equivalent of cone 35 (1,785° C.), a loss of weight of less than 2 percent, and a volume shrinkage of less than 2 percent at 1,530° C. Slag tests of olivine block in high-temperature contact with basic open-hearth steel slag have indicated that it has a better resistance than commercial magnesia brick. Tests on the fluxing effect of various materials showed that, of the substances tried, alumina lowered the melting temperature most and iron oxide gave less fluxing action. More than 35 percent of magnesia and 50 percent of chromite were necessary before an appreciable raising of the refractoriness was noted. Petrographic examination showed that synthetic forsterite crystals could be developed at high temperature.

STRONTIUM MINERALS

A general review of the strontium industry appeared in *Minerals Yearbook, 1935* (p. 1232). No domestic production of strontium ore has been reported since 1918, and domestic needs are supplied by imports which are shown in the following table.

Strontium minerals and chemicals imported for consumption in the United States, 1925-36

¹ Oxide included under carbonate.

VERMICULITE

The production of vermiculite in 1936, as reported to the Bureau of Mines by five producers, was 61,770 short tons. Sales aggregated 16,733 tons valued at \$184,387, of which 15,596 tons valued at \$151,858 were sold crude and 1,137 tons valued at \$32,529 were expanded or otherwise processed or refined at or near the mine.

The Montana companies continued to furnish the bulk of the output, notwithstanding greatly increased activity in Wyoming and Colorado. The Universal Insulation Co. marketed a plastic insulating

cement and a light-weight insulating concrete in addition to other vermiculite products. F. E. Schundler & Co., which operates processing plants at Joliet, Ill., and Long Island City, N. Y., completed arrangements in 1936 for exporting vermiculite. An English company, known as British Vermiculite Products, Ltd., has been formed, and an expanding plant installed in Stratford. The Colorado Vermiculite Co., Inc., of Guthrie, Colo., has erected an expanding plant in Fremont County. The Vermiculite Co. of America, Hillside, Colo. (which acquired various properties formerly held by the Allied Minerals Co. of Austin, Minn.), reported grading and cleaning equipment as under construction. The Associated Minerals, Inc., of Austin, Minn., further developed its Colorado property. The Mikolite Co., Kansas City, Mo., not only produces house fill but also a full line of insulating plaster, acoustical plaster, roof insulation, and decorative finishes. This company, after experimenting with raw material from other States, has recently been using Wyoming vermiculite, which is said to differ from other vermiculite in that it expands like a sponge instead of like an accordion. The North Carolina vermiculites are not so readily adaptable for use in loose house fill as the western vermiculites because they are too friable after calcining, but they are used fairly extensively in molded insulation and wallboard; they seem to adhere to a bond better than the more leathery type. Shipments were reported in 1936 by the Georgia-Carolina Minerals Corporation and the Vercolite Corporation, both of Franklin, N. C.

According to a recent report¹² of the Tennessee Valley Authority, the tonnage of individual deposits of high-grade vermiculite in western North Carolina and north Georgia is not as large as was generally supposed a year or so ago. The veins, the best of which are selvage veins along contacts of peridotites and pyroxenites, range in width to a maximum of 25 feet, the average being less than 10 feet. No vermiculite mining has so far extended below 40 feet, as the operations are open-cut and the walls are heavily jointed. Gangue minerals are picked out by hand. If the fines are not wanted, they are removed by being passed over a screen, although, with increased demand for fines free from clay and other impurities, log washers may come into use.

		Conclusion.....	1464

A small increase in the number of employees and a slight reduction in the aggregate number of man-hours of employment in the mining and quarrying industry of the United States in 1935 compared with 1934 were shown by reports furnished to the United States Bureau of Mines by operating companies. Preliminary reports for 1936 indicate a further increase in the number of men employed during that year and in the number of man-hours worked.

These statements are based upon an examination of complete reports for 1935 from operators of anthracite and bituminous-coal mines; stone quarries and related plants, such as cement mills, limekilns, rock crushers, and finishing plants; on reports from representative mines producing gold, silver, copper, lead, zinc, or other mineral; and on preliminary returns from various classes of mines and quarries for 1936.

Although the mineral industry includes the milling and smelting of ores, the production of petroleum and natural gas, and the manufacture of coke, statistics now available for 1935 and 1936 only cover mining, quarrying, and the preparation of such rock products as cement, lime, crushed rock, and sawed and finished stone.

Within the field covered by these operations, 697,402 men were employed in 1934, the latest year for which final and complete figures are available. Complete reports for most of the industry and partial reports for certain groups of metal mines indicate that the number of men at work in 1935 was approximately 709,000. Reports for 1936 from a relatively small number of plants suggest that the working force during that year may have reached 756,000 men, but the accuracy of this figure cannot be accepted until returns have been received from a much larger number of companies than have thus far furnished their annual reports to the United States Bureau of Mines. The indication of 756,000 employees in 1936 is based upon

the percentage of increase in employment shown by reports for that year compared with reports from identical plants operating during 1935.

Coal mining is by far the largest branch of the mining industry in the United States, whether measured by the number of men employed, the number of man-hours of labor performed during a normal year, or the quantity and value of mineral produced; it is also largest when measured by the number of men killed or injured by accidents that

FIGURE 119.—Trend of employment at mines and quarries in the United States, 1911-34.

occur while the men are at work. For this reason, most of the present review of employment and accidents during 1935 is devoted to coal mining, although quarrying, metal mining, and nonmetallic-mineral mining are discussed briefly to show the trends of employment and accidents during that year and to show similar trends through 1936 so far as revealed by preliminary returns from identical establishments that were active both in 1935 and 1936.

Employment and fatal-accident record of the mining and quarrying industries in the United States, 1911-35

EMPLOYMENT AND ACCIDENTS

BITUMINOUS-COAL MINES

Employment.—The total number of men employed in bituminous-coal mining has increased continuously since 1932, when the lowest level of the depression period was reached. In that year the number of workers employed was 406,380, a decrease of 19 percent compared with the working force employed in 1929. Additions to the mine pay rolls during the three succeeding years brought the number of workers employed in 1935 to within 8 percent of the predepression level. Scattering returns from a small number of companies indicate that the number of workers was increased further in 1936.

Outstanding coal-producing States in increasing employment since 1932 are Virginia and West Virginia in the East, Ohio and Michigan in the east north central area, and Missouri, Iowa, and South Dakota in the trans-Mississippi region. In all of these States employment in 1935 was greater than in 1929. On the other hand, employment in both Pennsylvania and Kentucky was still lagging behind the predepression level. Compared with 1929 a decrease of 6 percent is shown in the number of bituminous mine workers employed in Pennsylvania, and Kentucky shows a decrease of 11 percent.

In recent years there has been a marked shortening of the coal miner's workday. Although the trend toward a shorter workday has been evident for many years, 1930 was the first year in which the mining companies were specifically requested to indicate on their reports to the Bureau of Mines the aggregate number of man-hours of work performed at their properties as given on the books of the companies. The returns for that year showed that many companies had not then begun to keep a record of man-hours worked; on the other hand, a large number of companies did keep such records, and they reported the actual book figure to the Bureau. Those that did not maintain man-hour records reported to the Bureau the average number of employees, the number of days on which coal was produced,

and the number of hours constituting a standard working day at the mines; with this information, the number of man-hours worked at these mines was calculated and added to the number of man-hours worked at the other mines where actual book records of man-hours worked were maintained. Complete figures for 1930, as thus reported and calculated, revealed that the bituminous-coal mining industry in the United States operated an average of 8.13 hours per day per man employed in 1930. By 1935 many more companies were maintaining records of man-hours actually worked, and the reports for that year for the entire industry showed an average of 7.03 hours worked per man-day. Incomplete reports for 1936 indicate a slight increase in the length of workday over 1935.

It should be made clear that the total number of employees and the number of hours constituting a workday do not in themselves show the volume of employment in the coal-mining industry. The volume of employment depends, further, on the number of days on which the mines were in operation. Whether a mine is active or idle on a given day is determined largely by the presence or absence of orders for coal on the company's books; yet the working crew, in more or less normal numbers, must stand by and be available for work on any day of the year. In 1930, out of a possible working period of more than 300 days, the actual operating time of all bituminous-coal mines in the United States averaged only 187 days per man. In 1935 each employee averaged only 178 days of work, and even in 1929 the average employee had only 219 days of employment. This part-time employment, if spread over a year of 52 weeks, means that in 1930 the average period of employment was 29 hours per man per week; it was 25 hours in 1934 and 24 hours in 1935. In other words, the average coal miner averages about $3\frac{1}{2}$ 7-hour days per week throughout the year.

The aggregate number of man-hours worked at coal mines rises and falls with the increase and decrease in the quantity of coal produced, except as the relation between the two sets of figures may be affected by the increasing productivity of labor due to increased mechanization and other improvements in methods of production. Upward trends in total production are accompanied by *less*-pronounced upward trends in man-hours worked. By contrast, when the trend of total production is downward, *more*-pronounced downward trends in the number of man-hours worked are observed. The tendency of total man-hours to lag behind total production when the trend is upward and to fall more rapidly when the trend is downward is chiefly due, as previously stated, to the increasing quantity of coal produced per man-hour of labor performed. Production of bituminous coal in the United States reached a maximum in 1918; this was also the year of maximum number of man-hours worked at the mines. Compared with 1918, there was a drop in 1935 of 36 percent in total production and 54 percent in the total number of man-hours worked. In 1918 production averaged 0.463 ton per man-hour worked; in 1935 the average was 0.644 ton, an increase of 39 percent.

Accidents.—Coal mining ranks as one of the most hazardous of the major industries of the United States. Nevertheless, the number of lives lost from accidents has been reduced greatly in recent years. The annual loss of life in bituminous mines during the past 3 years has averaged only about half of what it was 20 years ago. In 1935,

for example, only 968 men were killed compared with 1,683 in 1915; in 1934 there were 958 fatalities compared with 1,859 in 1914; and in 1933 the total was only 833 against 2,167 in 1913.

Although it is clear that fewer men are now being killed by accidents at the mines than formerly, this fact does not necessarily indicate that the present-day coal miner is a better life-insurance risk than was the miner of 20 years ago. To make the individual miner more acceptable to a life-insurance company, his per-capita accident experience must be reduced. Whether or not this has been accomplished is quite independent of the actual number of fatal accidents reported from year to year in the coal-mining industry as a whole. The number of fatal accidents must be considered in relation to the number of men employed and the number of hours the men work in the mines.

Physical conditions underground undoubtedly have been improved. Operators and miners are more safety-minded than they were 20 years ago. Mining machinery is used more extensively than ever before. Machine-loading of coal at the face has largely replaced loading by hand shovel in many mines. Haulage cars and tracks have been improved. There is no doubt that good housekeeping is practiced by more and more coal-mining companies.

These evidences of progress in a large number of mines make possible a larger production of coal by the average employee for each day or hour he spends at work. Under these conditions it is manifest that fewer men, or at least fewer man-hours, are required to produce a given quantity of coal. With the 1935 average productivity per man-hour the tonnage produced by the entire industry in the prosperous year 1929 could have been produced with 35,000 fewer men than were actually employed that year. Moreover, this could have been accomplished without any change in the working time of the 1929 employee. The production of coal during 1915 could have been made with 165,000 fewer men than were employed during that year, also without any change in the working time of the 1915 employee.

With a reduction in the number of employees or man-hours as the productivity of labor increases, there must be a proportionate reduction in the number of accidents to hold the accident rate per employee or per man-hour to its former level. If the number of accidents is not thus proportionately reduced, the accident rate will rise; if accidents are reduced in greater proportion than men or man-hours, the accident rate will be lowered. From 1915 to 1935 the number of man-hours worked at the mines was reduced 40.8 percent, and the number of men killed was reduced 42.5 percent. Thus, efficiency in safety increased at a more rapid rate than did efficiency in the production of coal, and the fatality rate per million man-hours of employment was reduced from 1.722 to 1.673, a reduction of nearly 3 percent, although the average miner produced 42 percent more coal in an hour in 1935 than he did in 1915.

This point is often overlooked by those who are critical of the coal industry's accident record, and it is equally overlooked by others who are inclined to claim for the industry more credit than it merits.

Could operating conditions in coal mines remain static, we might reasonably expect accident-prevention measures to produce a constant downward trend in the accident rate; but conditions change continually, and the inherent hazards of mining would take an

increasing toll of human life were it not for the safety measures the operators and miners observe in their work. As the per-capita hazards increase with the declining number of employees, safety measures also must increase. Under these conditions, it should be recognized that progress in safety is being made if the accident rate does not rise as fast as the per-capita hazards increase, and especially is this true if the accident rate is kept on its former level. It should be recognized that safety measures are doubly effective when the accident rate per man-hour worked shows a downward trend when the inherent hazards of mining per man employed are increasing.

ANTHRACITE MINES

Employment.—The anthracite mines covered by Bureau of Mines statistics of employment and accidents are situated entirely in the eastern part of the State of Pennsylvania. Data on the few anthracite mines elsewhere in the United States are included with the statistics for bituminous-coal mines. Employment at the anthracite mines in Pennsylvania declined in 1935 compared with 1934, both as to number of workers and man-hours of work performed. Moreover, the average period of employment per man was less than in 1934. Reports from the operating companies showed a total of 102,848 men employed and 154,096,381 man-hours worked in 1935, a reduction of 5 percent and 14 percent, respectively, compared with 1934. The average employee worked 187 days, or 19 days less than the year before. No specific information as to employment is available for 1936.

Accidents.—Reports for 1935 showed that 274 employees were killed and 18,046 were injured by accidents at the mines, breakers, and dredges. These figures indicate a fatality rate of 1.78 per million man-hours of employment compared with 1.50 for the previous year and a nonfatal lost-time injury rate of 117.11 compared with 117.88 for 1934. During the 6 years (1930–35) for which comparable figures are available, the lowest accident rate (113.74) for fatal and nonfatal injuries was that for 1933. Although the combined rate for 1935 was only a fraction less than in 1934 and although it did not compare favorably with the rate for 1933 it was more favorable than the rates for the 3 years preceding 1933.

IRON-ORE MINES

Employment.—A larger volume of work performed and a reduction in the number of men employed was shown for 1935 compared with 1934 by final and complete reports received by the Bureau of Mines from operating companies. The reduction in number of employees was 9 percent, but a 2-percent gain was reported in the aggregate number of man-hours worked during the year. The working time for all operating mines averaged 219 days or 1,758 hours per man compared with 195 days or 1,558 hours per man in the preceding year. An average of 8 hours per shift was reported for both years. Preliminary reports for 1936 indicate large gains in employment over 1935, both in the number of men working and the man-hours of labor performed. According to the returns thus far received, the increase in 1936 over 1935 was probably as much as 30 percent. Notwithstanding this evidence of further recovery from the recent depression, the industry

no longer seems to require the working force it employed 15 or 20 years ago. Maximum employment was reached in the war year, 1917, when the working force was more than 57,000 men and when more than 16 million man-days of labor were required to produce the tonnage of that year. Much of this labor doubtless was utilized to produce iron for purposes connected directly or indirectly with the World War. But even in 1920, more than 45,000 men were employed and more than 13 million man-days were worked. By 1935 the number of employees had been reduced to 14,000 and the number of man-days to approximately 3 million. Although this reduction in employment may be attributed, in part, to the absence of need for iron for war purposes, and partly to incomplete recovery from the depression, perhaps the chief reason for the industry's present ability to operate with fewer men is the fact that methods of operation have been improved and, in consequence, each man-hour of labor is now more productive than formerly. Actual records of productivity per man-hour were not available until 1923, but since that year the output of iron ore in the United States per man-hour of labor performed has been tending upward. Other factors that contribute to a larger output per man-hour are the increasing proportion of total tonnage of ore now being obtained from open-pit mines compared with underground mines and the larger production of ore per man-hour made possible by using large power shovels in open-pit mining.

Accidents.—The iron-ore-mining industry is outstanding among the metal-mining industries of the United States for its low death and injury rates from accidents. In 1935 the accident rate was 18.7 per million man-hours of employment, having been reduced from 20.8 for the previous year. In one respect the record was less favorable than in the preceding year, the fatality rate being 0.89 in 1935 against 0.66 in 1934. Thus, the improvement in 1935 was in the field of nonfatal injuries rather than accidents causing the death of the injured employees. Except for 1932, when the combined accident rate for fatal and nonfatal injuries was 17.0 per million man-hours of employment, the corresponding rate of 18.7 for 1935 was the lowest accident rate and therefore the best safety record that the industry has ever had. The remarkable extent to which accidents have been eliminated from iron-ore mining is indicated by the low accident rates that have prevailed in recent years. So successful have the mining companies been in preventing accidents to their employees that the accident rate for 1935 was 82 percent lower than it was for 1911, the first year for which figures are available. Preliminary reports from the operating companies indicate that the accident rate was higher in 1936 than in 1935, but even if final returns should bear out this apparent increase the rate for 1936 was lower than that for any year preceding 1932.

COPPER MINES

Employment.—Although complete reports for copper mines for 1935 are not yet available, partial returns from the operators indicate substantial gains over 1934 in the number of men working and man-hours worked. Further increases are indicated by preliminary reports from the producing companies for 1936. The improvement in employment was general, virtually all copper-mining districts sharing in the gains. The industry employed 8,084 men in 1934, and it is probable that this figure was increased to approximately 9,500 in 1935.

The total volume of labor performed in 1934 was reported as 14,726,617 man-hours, which apparently was increased to about 20,800,000 man-hours in 1935.

Accidents.—Complete statistics on accidents at copper mines are not yet available for 1935, but incomplete figures show a large increase in the accident rate over 1934. For each million man-hours of employment during 1934, reports from producing companies showed 46.2 accidents. This rate apparently increased to approximately 68 accidents per million man-hours in 1935, and preliminary reports for 1936 indicate a further increase.

LEAD AND ZINC MINES (MISSISSIPPI VALLEY STATES)

Employment.—Figures covering identical mines operating during 1934 and 1935 in Kansas, Missouri, and Oklahoma—the principal lead-zinc producing States of the Mississippi Valley—and covering mines that employ about half the total number of men in the entire region, showed a slight reduction in the number of employees in 1935 and a more material falling off in the number of man-days and man-hours worked. The decreases were in Kansas and Oklahoma. Mines in Missouri reported gains in employees, man-days, and man-hours, but these gains were not extensive enough to overcome a decline in employment in the region as a whole. In 1936, according to preliminary returns, the number of workers and the volume of employment increased, Kansas and Missouri sharing in the gains and Oklahoma reporting a further decline.

Accidents.—Although Oklahoma reported a loss in employment in 1935 it was the only one of the three important lead-zinc producing States in the Mississippi Valley to report a better safety record. The accident rate for Oklahoma was lowered to such an extent that increased rates in Kansas and Missouri were more than overcome, so that the group rate for the three States was lower in 1935 than in 1934. This favorable showing apparently did not continue in 1936, as partial returns indicate higher accident rates for each of the three States and, consequently, for the district as a whole.

GOLD, SILVER, AND MISCELLANEOUS METAL MINES

Employment.—Employment and accident data for this group of mines reflect chiefly the experience of mines that produced gold and silver, but the figures also cover lead and zinc mines operating in States other than those in the Mississippi Valley; the figures also include data for mines that produced minor metals, such as quicksilver, manganese, etc.

Complete figures for this and several other classes of metal mines are not yet available for 1935, owing to the loss of one-third of the Bureau of Mines personnel several years ago and the inability of the small available force to complete the tabulation of returns from mining companies in time for inclusion of the figures in this publication. Such reports as have been tabulated cover approximately 34 percent of all men who work in this class of mines. These reports show increases in the number of employees, man-days, and man-hours for 1935. The increase in number of employees, according to these incomplete figures, was approximately 14 percent, and the gain in number of man-hours worked was about 20 percent.

Accidents.—The accident rate for mines producing gold, silver, and the other metals included in this group was 99.2 per million man-hours of employment in 1934. According to available returns, the rate for 1935 was lower than this, perhaps by as much as 6 percent, which would indicate that the rate will be about 93.3 per million man-hours worked in 1935. Early returns for 1936 indicate an increase over the accident rate for 1935.

NONMETALLIC-MINERAL MINES

Employment.—Included in this group are mines that produce gypsum, phosphate rock, sulphur, or any nonmetallic mineral except coal, sand, gravel, or clay. Nonmetallic-mineral mines, as thus defined, reported a total of 8,339 men employed during 1935 compared with 8,234 men in the previous year. The total working time for all employees equaled 16,168,307 man-hours, an increase of a little more than 6 percent over 1934. The average employee was at work 1,939 hours during the year, which compares favorably with the previous year's average of 1,844. No data are available for 1936 for mines included in this group.

Accidents.—The mining of other nonmetallic minerals is usually attended by fewer accidents in proportion to the volume of employment than is the mining of coal, and, with the exception of iron mining, the record for the nonmetallic group is also usually more favorable than that of metal mines. The accident rate for mines in the non-metallic group was 50.7 per million man-hours of employment in 1935, a reduction from the rate of 52.3 for the year 1934. Reports have not yet been compiled to reveal the rate for 1936.

CEMENT

Employment.—A slight reduction in the number of employees engaged in quarrying and an equally slight increase in the number of men working at the cement mills were reported by the operating companies for 1935. The reduction and increase extended to the number of man-hours worked at the quarries and mills, respectively, a net increase being reported for the industry as a whole. The returns for both quarries and mills showed 24,416 men employed and 39,243,018 man-hours worked, the average working time per employee being 227 days (1,607 man-hours). A further increase in the number of workers and a very material increase in the number of man-hours worked were shown for 1936 by reports that, though not covering all companies, reflect conditions in more than 80 percent of the industry based on the number of men employed.

Accidents.—The cement industry ranks as the leader in safety among the various stone-quarrying industries of the United States. For a number of years the accident rate for cement mills and quarries has been low, much lower than for any other important branch of the quarrying industry. The rate for 1934, which represented 12.6 lost-time accidents per million man-hours of employment, was lowered to 9.5 in 1935, a reduction of more than 24 percent. Unfortunately, the accident rate increased in 1936, according to incomplete returns for that year, the reports indicating an increase large enough to raise the rate for the year back approximately to that for 1934.

LIMESTONE

Employment.—The number of men employed at quarries that produce limestone for purposes other than the manufacture of cement was 30,973 in 1935. This number is not strictly comparable with the number (24,119) reported for 1934 because many small operations were canvassed for 1935 that were not canvassed in the preceding year. Statistics for identical plants that were active during both years indicate that the number of employees was slightly less in 1935 than in 1934 and that there was also a small reduction in the number of man-hours of labor performed. The entire canvass for 1935 showed a total of 45,197,391 man-hours worked, an average of 1,459 hours per employee. A slight reduction in the length of the workday was reported, from 8.1 hours per day in 1934 to 7.8 hours per day in 1935, based upon reports for identical plants. A few reports showed more employment in 1936, both in total number of employees and total number of man-hours worked, over the record of the identical establishments for 1935.

Accidents.—Progress was reported in preventing accidents in 1935 compared with 1934, both as to all establishments canvassed for those 2 years and as to identical establishments active in 1934 and 1935. The accident rate was reduced from 57.3 fatal and nonfatal lost-time-injuries per million man-hours of employment in 1934 to 53.9 per million hours in 1935, with preliminary reports for 1936 indicating a further slight improvement over the 1935 record.

MARBLE

Employment.—With approximately the same number of men working as in the preceding year, companies engaged in the operation of marble quarries and finishing plants reported a substantial gain in the number of man-hours worked in 1935. The average number of men employed was 2,441 compared with 2,488 in 1934, but the volume of employment, as measured by the number of man-hours of labor performed during the year, increased from 3,508,983 in 1934 to 4,016,819 in 1935, a gain of 14 percent. The average employee worked 1,646 hours during the year, a gain of 236 hours over the average number of hours worked in the preceding year. The average length of working day, weighted for all plants and for all men, was 7.8 hours, a slight increase over the average of 7.5 hours per day in 1934. Information available for 1936 and covering about two-thirds of the men employed in the marble industry shows an increase in employment in 1936 over 1935.

Accidents.—One fatal accident and 176 nonfatal lost-time injuries occurred among the employees at marble quarries and plants during 1935. These figures indicate an accident rate of 44.1 per million man-hours of employment compared with a rate of 43.3 for the preceding year. Preliminary reports for 1936 present a material reduction in the accident rate for that year.

SANDSTONE

Employment.—Reports from companies engaged in the production of sandstone during 1935 showed an average working force of 2,739 men and a total of 3,688,135 man-hours of labor performed. As these figures cover some companies that had not previously been

included in the Bureau's annual employment canvasses they are not entirely comparable with similar figures for 1934. Reports from identical companies for both years showed approximately the same number of employees in 1935 as in the previous year, but they also showed an increase of 8 percent in the total number of man-hours worked. The identical companies reporting this increase in man-hours worked represented about half of the industry. Complete reports from all companies operating during 1935 showed an average period of employment of 167 days or 1,347 hours per man and an average daily shift of 8.1 hours.

Accidents.—The accident rate for the sandstone industry remained virtually unchanged in 1935, whether measured by reports from identical companies or by comparing the complete canvass for 1935 with the somewhat less complete canvass for 1934. Complete returns for 1935 showed that 243 men had been injured by nonfatal accidents. The accident rate for the year was 65.9 per million man-hours of employment compared with 64 for 1934. Information for 1936 is still too meager to indicate the accident rate for that year.

GRANITE

Employment.—Granite quarries and finishing plants reported a reduction in the number of employees and in the number of man-hours worked in 1935 compared with 1934. That these losses were recovered in 1936, however, is indicated by preliminary reports for that year which represent something less than one-fifth of the industry. As far as may be judged from these early reports, the gain over 1935 was about 20 percent in number of men employed and approximately 27 percent in number of man-hours worked. Final statistics for 1935 showed 6,877 employees and 10,555,416 man-hours of work performed compared with 7,807 men and 11,000,155 man-hours in 1934. The aggregate working time for all plants in 1935 averaged 1,535 hours per man employed. The weighted average length of workday was 7.6 hours. These figures represent more hours of work per man for the year and a slightly longer workday, as the reports for 1934 showed 1,409 hours per man and an average workday of 7.3 hours.

Accidents.—The industry's safety record improved in 1935, according to final reports from the operating companies, which revealed a rate of 54.6 per million man-hours worked in 1935, as against 71.9 in 1934. A further slight reduction in the accident rate is shown by partial returns for 1936.

TRAP ROCK

Employment.—Reports from operators of trap-rock quarries for 1935 showed a total of 3,496 men employed and 4,235,223 man-hours of labor performed. These figures represent a large increase both in number of employees and in man-hours worked over the corresponding statistics for 1934. However, as the canvass of the industry was more complete in 1935 than in the preceding year, the larger number of reporting companies for 1935 must be responsible for some of the increase. That the industry distinctly improved in 1935 is shown by the reports from operating companies, which revealed a much larger quantity of stone produced during 1935 than in the preceding year. Although the output of building stone declined in 1935, a very marked

increase occurred in the quantity of rubble produced.¹ The reports from operating companies for 1935, which, as stated, are more complete than those of the previous year, showed an average working time of 154 days, or 1,211 hours of employment, per man.

Accidents.—Accidents at trap-rock quarries were reduced to a marked degree in 1935, as shown by a substantial lowering of the accident rate per million man-hours of employment. For the industry as a whole the rate was 53.6, a reduction of 34 percent from the previous year's rate of 81.1. This improvement corresponds with that shown by reports from identical establishments for the 2 years, which showed a rate of 66.7 for 1934 and 42.1 for 1935.

SLATE

Employment.—Reports from operators of slate quarries for 1935 revealed a total working force of 2,063 men and a volume of employment equal to 3,097,339 man-hours of labor. These figures indicate that the average employee worked 1,501 hours during the year. The plants were in operation for an average of 184 days per man, the average working shift being 8.2 hours. As the Bureau of Mines canvass of the slate industry was more complete in 1935 than in 1934, statistics for 1935 are not entirely comparable with those for the previous year. Identical establishments operated during both years showed substantial gains in number of men working and in number of man-days and man-hours of labor performed in 1935. Even larger increases in number of employees, man-days, and man-hours over the record for 1934 are indicated by complete returns for 1935 due to the increase in number of establishments that reported for 1935.

Accidents.—The accident rate for slate quarries was higher in 1935 than in 1934. This fact is revealed by reports covering identical plants that were active during both years; the reports show a rate of 58.0 per million man-hours worked in 1934 and 62.8 per million man-hours in 1935. The entire canvass for 1935 revealed an accident rate of 54.9 compared with 58.1, as given by the somewhat less complete canvass for the preceding year.

CONCLUSION

The mining and quarrying industries of the United States apparently have achieved efficiency of operation that no longer demands so large a number of workers as were employed heretofore. Complete statistics for the industry, beginning with 1911, show a total of 1,005,281 men employed. The number reached a maximum in 1923, when 1,078,270 employees were reported to the Bureau of Mines by the operating companies. Only 637,777 workers were employed in 1932, the lowest number. An upward trend brought the number of employees to 697,402 in 1934, the latest year for which complete data are available. As stated previously, this figure was increased further in 1935 and 1936, according to reports for 1935 from nearly all operating companies and according to preliminary returns for 1936.

Maximum employment, as indicated by the number of man-days of labor performed, a standard of measurement used in the absence of a long-time record of man-hours worked, was reached in 1917 during

¹ Oliver Bowles, Carl A. Gnam, and A. T. Coons, Stone: Minerals Yearbook, 1936, Bureau of Mines, p. 820.

the World War, when operating companies reported 269,482,848 man-days. This number declined to a minimum of 100,954,646 man-days in 1932, when the number of workers was also lowest. Employment increased to 131,771,709 man-days in 1934, and was increased further in the 2 years following, according to reports now available but not complete for the entire industry.

The death rate from accidents has been reduced 30 percent since 1911, and it was lower in 1934 than ever before. Likewise, the non-fatal-injury rate was lower in 1934 than at any time since 1930, the earliest year covered by reports of injuries for all branches of mining and quarrying.

If the most favorable fatality rate (that reported for 1934) had prevailed during all years since 1911, nearly 13,000 lives would have been saved during that period. The actual number of fatalities during the 24-year period 1911 to 1934 was 65,188. This number would have been 52,337 if the rate for 1934 had prevailed.

What the long-time trend of employment and accidents in the mineral industries may prove to be is perhaps impossible to forecast because of the impossibility of determining the effects of varying trends of technological improvements in methods of mining, of operating mines with leaner ore bodies and thinner seams of coal, of the character of labor force that future working conditions may attract to the mines, of substitution of mineral products with changing prices, and of unpredictable markets for mineral commodities. There can be little doubt, however, that the next decade or so will witness only moderate increases in the number of men employed, with relatively larger increases in total man-hours worked to meet unusual demands for larger quantities of mineral products. Small increases in the demand for minerals may be met by the increasing productivity of labor per man-hour worked.

In the realm of safety, fewer accidents may be expected in proportion to the number of men employed. Recognition of the hazards involved in mining has spread to large sections of the industry, not only among the masses of workers but among supervisory officials and owners of mines. Although the value of mechanical safeguards is not to be discounted, accident prevention is largely a matter of safety education of mining officials and their employees. The progress the mining industry has made during the past few years in lowering the death and injury rate from accidents should be credited more to safety education than to any other single factor. As long as safety education is continued without interruption, a downward trend in the industry's accident rate may be expected. The greatest danger that can threaten the safety movement in mining is the false idea that the movement may proceed temporarily under its own momentum when funds are low and profits small or nonexistent.
